Abstract

This guide describes the settings for Red Hat build of Apache Camel components.

Table of Contents

PREFACE	55
MAKING OPEN SOURCE MORE INCLUSIVE	55
CHAPTER 1. COMPONENT STARTERS	56
CHAPTER 2. AMQP	72
2.1. DEPENDENCIES	72
2.2. URI FORMAT	72
2.3. CONFIGURING OPTIONS	72
2.3.1. Configuring Component Options	72
2.3.2. Configuring Endpoint Options	72
2.4. COMPONENT OPTIONS	73
2.5. ENDPOINT OPTIONS	92
2.5.1. Path Parameters (2 parameters)	93
2.5.2. Query Parameters (96 parameters)	93
2.6. USAGE	112
2.7. CONFIGURING AMQP COMPONENT	113
2.8. USING TOPICS	114
2.9. SPRING BOOT AUTO-CONFIGURATION	114
CHAPTER 3. AVRO	133
3.1. DEPENDENCIES	133
3.2. AVRO DATAFORMAT OPTIONS	133
3.3. AVRO DATA FORMAT USAGE	133
3.4. SPRING BOOT AUTO-CONFIGURATION	134
CHAPTER 4. AVRO JACKSON	135
4.1. DEPENDENCIES	135
4.2. CONFIGURING THE SCHEMARESOLVER	135
4.3. AVRO JACKSON OPTIONS	135
4.4. USING CUSTOM AVROMAPPER	137
4.5. SPRING BOOT AUTO-CONFIGURATION	137
CHAPTER 5. AWS CLOUDWATCH	141
5.1. DEPENDENCIES	141
5.2. URI FORMAT	141
5.3. CONFIGURING OPTIONS	141
5.3.1. Configuring Component Options	141
5.3.2. Configuring Endpoint Options	142
5.4. COMPONENT OPTIONS	142
5.5. ENDPOINT OPTIONS	144
5.5.1. Path Parameters (1 parameters)	144
5.5.2. Query Parameters (16 parameters)	144
5.6. USAGE	146
5.6.1. Static credentials vs Default Credential Provider	146
5.6.2. Message headers evaluated by the CW producer	146
5.6.3. Advanced CloudWatchClient configuration	147
5.7. EXAMPLES	147
5.7.1. Producer Example	147
5.8. SPRING BOOT AUTO-CONFIGURATION	147
CHAPTER 6. AWS DYNAMODB	150
6.1. DEPENDENCIES	150

6.2. URI FORMAT	150
6.3. CONFIGURING OPTIONS	150
6.3.1. Configuring Component Options	150
6.3.2. Configuring Endpoint Options	150
6.4. COMPONENT OPTIONS	151
6.5. ENDPOINT OPTIONS	153
6.5.1. Path Parameters (1 parameters)	154
6.5.2. Query Parameters (20 parameters)	154
6.6. USAGE	156
6.6.1. Static credentials vs Default Credential Provider	156
6.6.2. Message headers evaluated by the DDB producer	156
6.6.3. Message headers set during BatchGetItems operation	158
6.6.4. Message headers set during DeleteItem operation	158
6.6.5. Message headers set during DeleteTable operation	158
6.6.6. Message headers set during DescribeTable operation	159
6.6.7. Message headers set during GetItem operation	160
6.6.8. Message headers set during PutItem operation	160
6.6.9. Message headers set during Query operation	160
6.6.10. Message headers set during Scan operation	160
6.6.11. Message headers set during UpdateItem operation	161
6.6.12. Advanced AmazonDynamoDB configuration	161
6.7. SUPPORTED PRODUCER OPERATIONS	161
6.8. EXAMPLES	161
6.8.1. Producer Examples	161
6.9. SPRING BOOT AUTO-CONFIGURATION	162
CHAPTER 7. AWS KINESIS	167
7.1. DEPENDENCIES	167
7.2. URI FORMAT	167
7.3. CONFIGURING OPTIONS	167
7.3.1. Configuring Component Options	167
7.3.2. Configuring Endpoint Options	168
7.4. COMPONENT OPTIONS	168
7.5. ENDPOINT OPTIONS	173
7.5.1. Path Parameters (1 parameters)	174
7.5.2. Query Parameters (50 parameters)	174
7.6. MESSAGE HEADERS	181
7.7. USAGE	182
7.7.1. Batch Consumer	182
7.7.2. Batch Producer	182
7.7.3. Static credentials, Default Credential Provider and Profile Credentials Provider	182
7.7.4. AmazonKinesis configuration	183
7.7.5. Providing AWS Credentials	183
7.7.6. AWS Kinesis KCL Consumer	183
7.8. SPRING BOOT AUTO-CONFIGURATION	183
CHAPTER 8. AWS 2 LAMBDA	192
8.1. DEPENDENCIES	192
8.2. URI FORMAT	192
8.3. CONFIGURING OPTIONS	192
8.3.1. Configuring Component Options	192
8.3.2. Configuring Endpoint Options	193
8.4. COMPONENT OPTIONS	193

8.5. ENDPOINT OPTIONS	195
8.5.1. Path Parameters (1 parameters)	196
8.5.2. Query Parameters (14 parameters)	196
8.6. USAGE	198
8.6.1. Static credentials vs Default Credential Provider	198
8.6.2. Message headers evaluated by the Lambda producer	199
8.7. LIST OF AVAILABLE OPERATIONS	202
8.8. EXAMPLES	203
8.8.1. Producer Example	203
8.8.2. Producer Examples	203
8.9. USING A POJO AS BODY	203
8.10. DEPENDENCIES	204
8.11. SPRING BOOT AUTO-CONFIGURATION	204
CHAPTER 9. AWS S3 STORAGE SERVICE	207
9.1. DEPENDENCIES	207
9.2. URI FORMAT	207
9.3. CONFIGURING OPTIONS	207
9.3.1. Configuring Component Options	207
9.3.2. Configuring Endpoint Options	208
9.4. COMPONENT OPTIONS	208
9.5. ENDPOINT OPTIONS	214
9.5.1. Path Parameters (1 parameters)	214
9.5.2. Query Parameters (68 parameters)	214
9.6. BATCH CONSUMER	222
9.7. USAGE	222
9.7.1. Message headers evaluated by the S3 producer	222
9.7.2. Message headers set by the S3 producer	224
9.7.3. Message headers set by the S3 consumer	224
9.7.4. S3 Producer operations	225
9.7.5. Advanced AmazonS3 configuration	226
9.7.6. Use KMS with the S3 component	226
9.7.7. Static credentials vs Default Credential Provider	226
9.7.8. S3 Producer Operation examples	226
9.8. STREAMING UPLOAD MODE	229
9.9. BUCKET AUTOCREATION	231
9.10. MOVING STUFF BETWEEN A BUCKET AND ANOTHER BUCKET	231
9.11. MOVEAFTERREAD CONSUMER OPTION	231
9.12. USING CUSTOMER KEY AS ENCRYPTION	232
9.13. USING A POJO AS BODY	232
9.14. CREATE S3 CLIENT AND ADD COMPONENT TO REGISTRY	232
9.15. DEPENDENCIES	233
9.16. SPRING BOOT AUTO-CONFIGURATION	233
CHAPTER 10. AWS SIMPLE NOTIFICATION SYSTEM (SNS)	240
10.1. DEPENDENCIES	240
10.2. URI FORMAT	240
10.3. CONFIGURING OPTIONS	240
10.3.1. Configuring Component Options	240
10.3.2. Configuring Endpoint Options	241
10.4. COMPONENT OPTIONS	241
10.5. ENDPOINT OPTIONS	244
10.5.1. Path Parameters (1 parameters)	244

10.5.2. Query Parameters (23 parameters)	244
10.6. USAGE	247
10.6.1. Static credentials vs Default Credential Provider	247
10.6.2. Message headers evaluated by the SNS producer	247
10.6.3. Message headers set by the SNS producer	247
10.6.4. Advanced AmazonSNS configuration	248
10.6.5. Create a subscription between an AWS SNS Topic and an AWS SQS Queue	248
10.7. TOPIC AUTOCREATION	248
10.8. SNS FIFO	248
10.8.1. SNS Fifo Topic Message group Id Strategy and message Deduplication Id Strategy	249
10.9. EXAMPLES	249
10.9.1. Producer Examples	249
10.10. DEPENDENCIES	249
10.11. SPRING BOOT AUTO-CONFIGURATION	250
CHAPTER 11. AWS SIMPLE QUEUE SERVICE (SQS)	253
11.1. DEPENDENCIES	253
11.2. URI FORMAT	253
11.3. CONFIGURING OPTIONS	253
11.3.1. Configuring Component Options	253
11.3.2. Configuring Endpoint Options	254
11.4. COMPONENT OPTIONS	254
11.5. ENDPOINT OPTIONS	259
11.5.1. Path Parameters (1 parameters)	259
11.5.2. Query Parameters (61 parameters)	259
11.6. BATCH CONSUMER	266
11.7. USAGE	267
11.7.1. Static credentials vs Default Credential Provider	267
11.7.2. Message headers set by the SQS producer	267
11.7.3. Message headers set by the SQS consumer	267
11.7.4. Advanced AmazonSQS configuration	268
11.7.5. Creating or updating an SQS Queue	268
11.7.6. DelayQueue VS Delay for Single message	268
11.7.7. Server Side Encryption	268
11.8. JMS-STYLE SELECTORS	268
11.9. AVAILABLE PRODUCER OPERATIONS	269
11.10. SEND MESSAGE	269
11.11. SEND BATCH MESSAGE	269
11.12. DELETE SINGLE MESSAGE	270
11.13. LIST QUEUES	270
11.14. PURGE QUEUE	270
11.15. QUEUE AUTOCREATION	270
11.16. SEND BATCH MESSAGE AND MESSAGE DEDUPLICATION STRATEGY	270
11.17. DEPENDENCIES	271
11.18. SPRING BOOT AUTO-CONFIGURATION	271
CHAPTER 12. AWS SECRETS MANAGER	277
12.1. DEPENDENCIES	277
12.2. URI FORMAT	277
12.3. CONFIGURING OPTIONS	277
12.3.1. Configuring Component Options	277
12.3.2. Configuring Endpoint Options	278
12.4. COMPONENT OPTIONS	278

12.5. ENDPOINT OPTIONS	282
12.5.1. Path Parameters (1 parameters)	282
12.5.2. Query Parameters (19 parameters)	282
12.5.3. Static credentials, Default Credential Provider and Profile Credentials Provider	287
12.5.4. Using AWS Secrets Manager Property Function	288
12.5.5. Automatic Camel context reloading on Secret Refresh	290
12.5.6. Automatic Camel context reloading on Secret Refresh with Eventbridge and AWS SQS Services	291
12.6. MESSAGE HEADERS	292
12.6.1. Secrets Manager Producer operations	293
12.7. SPRING BOOT AUTO-CONFIGURATION	294
CHAPTER 13. AZURE KEY VAULT	298
13.1. DEPENDENCIES	298
13.2. URI FORMAT	298
13.3. CONFIGURING OPTIONS	298
13.3.1. Configuring Component Options	298
13.3.2. Configuring Endpoint Options	298
13.4. COMPONENT OPTIONS	299
13.5. ENDPOINT OPTIONS	299
13.5.1. Path Parameters (1 parameters)	300
13.5.2. Query Parameters (7 parameters)	300
13.6. USAGE	301
13.6.1. Using Azure Key Vault Property Function	301
13.6.2. Automatic Camel context reloading on Secret Refresh	303
13.6.3. Automatic Camel context reloading on Secret Refresh - Required Infrastructure's creation	304
13.7. MESSAGE HEADERS	306
13.7.1. Azure Key Vault Producer operations	306
13.8. EXAMPLES	306
13.8.1. Producer Examples	306
13.9. SPRING BOOT AUTO-CONFIGURATION	307
CHAPTER 14. AZURE SERVICEBUS	308
14.1. DEPENDENCIES	308
14.2. CONFIGURING OPTIONS	308
14.2.1. Configuring Component Options	308
14.2.2. Configuring Endpoint Options	308
14.3. COMPONENT OPTIONS	309
14.4. ENDPOINT OPTIONS	313
14.4.1. Path Parameters (1 parameters)	313
14.4.2. Query Parameters (25 parameters)	313
14.5. ASYNC CONSUMER AND PRODUCER	317
14.6. MESSAGE HEADERS	317
14.6.1. Message Body	321
14.6.2. Azure ServiceBus Producer operations	321
14.6.3. Azure ServiceBus Consumer operations	322
14.6.3.1. Examples	322
14.7. SPRING BOOT AUTO-CONFIGURATION	323
CHAPTER 15. AZURE STORAGE BLOB SERVICE	327
15.1. DEPENDENCIES	327
15.2. URI FORMAT	327
15.3. CONFIGURING OPTIONS	327
15.3.1. Configuring Component Options	327
15.3.2. Configuring Endpoint Options	328

15.4. COMPONENT OPTIONS	328
15.5. ENDPOINT OPTIONS	333
15.5.1. Path Parameters (2 parameters)	333
15.5.2. Query Parameters (50 parameters)	334
15.6. USAGE	342
15.6.1. Message headers	342
15.6.2. Message headers set by either component producer or consumer	348
15.6.3. Advanced Azure Storage Blob configuration	351
15.6.4. Automatic detection of BlobServiceClient client in registry	352
15.6.5. Azure Storage Blob Producer operations	352
15.6.6. Consumer Examples	354
15.6.7. Producer Operations Examples	355
15.6.8. SAS Token generation example	360
15.7. SPRING BOOT AUTO-CONFIGURATION	361
CHAPTER 16. AZURE STORAGE QUEUE SERVICE	366
16.1. DEPENDENCIES	366
16.2. URI FORMAT	366
16.3. CONFIGURING OPTIONS	366
16.3.1. Configuring Component Options	366
16.3.2. Configuring Endpoint Options	367
16.4. COMPONENT OPTIONS	367
16.5. ENDPOINT OPTIONS	370
16.5.1. Path Parameters (2 parameters)	370
16.5.2. Query Parameters (31 parameters)	370
16.6. USAGE	375
16.6.1. Message headers evaluated by the component producer	375
16.6.2. Message headers set by either component producer or consumer	377
16.6.3. Advanced Azure Storage Queue configuration	378
16.6.4. Automatic detection of QueueServiceClient client in registry	378
16.6.5. Azure Storage Queue Producer operations	378
16.6.6. Consumer Examples	379
16.6.7. Producer Operations Examples	380
16.6.8. Development Notes (Important)	382
16.7. SPRING BOOT AUTO-CONFIGURATION	382
CHAPTER 17. BEAN	385
17.1. DEPENDENCIES	385
17.2. URI FORMAT	385
17.3. CONFIGURING OPTIONS	385
17.3.1. Configuring Component Options	385
17.3.2. Configuring Endpoint Options	385
17.4. COMPONENT OPTIONS	386
17.5. ENDPOINT OPTIONS	387
17.5.1. Path Parameters (1 parameters)	387
17.5.2. Query Parameters (5 parameters)	388
17.6. EXAMPLES	389
17.7. BEAN AS ENDPOINT	389
17.8. JAVA DSL BEAN SYNTAX	390
17.9. BEAN BINDING	390
17.10. SPRING BOOT AUTO-CONFIGURATION	390
CHAPTER 18. BEANIO	394
18.1. DEPENDENCIES	394

18.2. OPTIONS	394
18.3. USAGE	402
18.4. SPRING BOOT AUTO-CONFIGURATION	404
CHAPTER 19. BEAN VALIDATOR	406
19.1. DEPENDENCIES	406
19.2. URI FORMAT	406
19.3. CONFIGURING OPTIONS	406
19.3.1. Configuring Component Options	406
19.3.2. Configuring Endpoint Options	406
19.4. COMPONENT OPTIONS	407
19.5. ENDPOINT OPTIONS	408
19.5.1. Path Parameters (1 parameters)	408
19.5.2. Query Parameters (8 parameters)	408
19.6. EXAMPLE	409
19.7. SPRING BOOT AUTO-CONFIGURATION	412
CHAPTER 20. BINDY	414
20.1. DEPENDENCIES	415
20.2. OPTIONS	415
20.3. ANNOTATIONS	415
20.3.1. 1. CsvRecord	416
20.3.2. 2. Link	420
20.3.3. 3. DataField	421
20.3.4. 4. FixedLengthRecord	427
20.3.5. 5. Message	435
20.3.6. 6. KeyValuePairField	436
20.3.7. 7. Section	438
20.3.8. 8. OneToMany	439
20.3.9. 9. BindyConverter	442
20.3.10. 10. FormatFactories	442
20.4. SUPPORTED DATATYPES	443
20.5. USING THE JAVA DSL	444
20.5.1. Setting locale	444
20.5.2. Unmarshaling	444
20.5.3. Marshaling	445
20.6. USING SPRING XML	445
20.7. DEPENDENCIES	446
20.8. SPRING BOOT AUTO-CONFIGURATION	447
CHAPTER 21. BROWSE	449
21.1. DEPENDENCIES	449
21.2. URI FORMAT	449
21.3. CONFIGURING OPTIONS	449
21.3.1. Configuring Component Options	449
21.3.2. Configuring Endpoint Options	449
21.4. COMPONENT OPTIONS	450
21.5. ENDPOINT OPTIONS	451
21.5.1. Path Parameters (1 parameters)	451
21.5.2. Query Parameters (4 parameters)	451
21.6. SAMPLE	452
21.7. SPRING BOOT AUTO-CONFIGURATION	452
CHAPTER 22. CASSANDRA CQL	454

22.1. DEPENDENCIES	454
22.2. CONFIGURING OPTIONS	454
22.2.1. Configuring Component Options	454
22.2.2. Configuring Endpoint Options	454
22.3. COMPONENT OPTIONS	455
22.4. ENDPOINT OPTIONS	456
22.4.1. Path Parameters (4 parameters)	456
22.4.2. Query Parameters (30 parameters)	456
22.5. ENDPOINT CONNECTION SYNTAX	461
22.6. MESSAGES	461
22.6.1. Incoming Message	461
22.6.2. Outgoing Message	461
22.7. REPOSITORIES	462
22.8. IDEMPOTENT REPOSITORY	462
22.9. AGGREGATION REPOSITORY	463
22.10. EXAMPLES	463
22.11. SPRING BOOT AUTO-CONFIGURATION	464
CHAPTER 23. CICS	465
23.1. DEPENDENCIES	465
23.2. URI FORMAT	465
23.3. CONFIGURING OPTIONS	466
23.3.1. Configuring Component Options	466
23.3.2. Configuring Endpoint Options	466
23.4. COMPONENT OPTIONS	466
23.5. ENDPOINT OPTIONS	468
23.5.1. Path Parameters (2 parameters)	468
23.5.2. Query Parameters (15 parameters)	468
23.6. MESSAGE HEADERS	470
23.7. SAMPLES	474
23.7.1. Using Commarea	474
23.7.2. Using Channel with a single input container	474
23.7.3. Using Channel with multiple input container	475
23.8. SPRING BOOT AUTO-CONFIGURATION	475
CHAPTER 24. CONSTANT	478
24.1. DEPENDENCIES	478
24.2. CONSTANT OPTIONS	478
24.3. EXAMPLE	478
24.3.1. Specifying type of value	479
24.4. LOADING CONSTANT FROM EXTERNAL RESOURCE	479
24.5. DEPENDENCIES	479
24.6. SPRING BOOT AUTO-CONFIGURATION	479
CHAPTER 25. CONTROL BUS	497
25.1. COMMANDS	497
25.2. DEPENDENCIES	497
25.3. CONFIGURING OPTIONS	497
25.3.1. Configuring Component Options	498
25.3.2. Configuring Endpoint Options	498
25.4. COMPONENT OPTIONS	498
25.5. ENDPOINT OPTIONS	499
25.5.1. Path Parameters (2 parameters)	499
25.5.1.1. Query Parameters (6 parameters)	500

25.6. USING ROUTE COMMAND	502
25.7. GETTING PERFORMANCE STATISTICS	502
25.8. USING SIMPLE LANGUAGE	503
25.9. SPRING BOOT AUTO-CONFIGURATION	503
CHAPTER 26. CRON	505
26.1. DEPENDENCIES	505
26.2. CONFIGURING OPTIONS	505
26.2.1. Configuring Component Options	505
26.2.2. Configuring Endpoint Options	506
26.3. COMPONENT OPTIONS	506
26.4. ENDPOINT OPTIONS	507
26.4.1. Path Parameters (1 parameters)	507
26.4.2. Query Parameters (4 parameters)	507
26.5. USAGE	508
26.6. SPRING BOOT AUTO-CONFIGURATION	508
CHAPTER 27. CRYPTO (JCE)	510
27.1. DEPENDENCIES	510
27.2. INTRODUCTION	510
27.3. URI FORMAT	510
27.4. CONFIGURING OPTIONS	511
27.4.1. Configuring Component Options	511
27.4.2. Configuring Endpoint Options	511
27.5. COMPONENT OPTIONS	511
27.6. ENDPOINT OPTIONS	515
27.6.1. Path Parameters (2 parameters)	515
27.6.2. Query Parameters (19 parameters)	516
27.7. MESSAGE HEADERS	519
27.8. USING	520
27.8.1. Raw keys	520
27.8.2. KeyStores and Aliases.	520
27.8.3. Changing JCE Provider and Algorithm	521
27.8.4. Changing the Signature Message Header	521
27.8.5. Supplying Keys dynamically.	522
27.9. SPRING BOOT AUTO-CONFIGURATION	522
CHAPTER 28. CSIMPLE	533
28.1. DEPENDENCIES	533
28.2. DIFFERENT BETWEEN CSIMPLE AND SIMPLE	533
28.2.1. Additional CSimple functions	533
28.3. COMPILATION	534
28.3.1. Using camel-csimple-maven-plugin	534
28.3.2. Using camel-csimple-joor	536
28.4. CSIMPLE LANGUAGE OPTIONS	536
28.5. LIMITATIONS	536
28.6. AUTO IMPORTS	537
28.7. CONFIGURATION FILE	537
28.8. SEE ALSO	537
28.9. SPRING BOOT AUTO-CONFIGURATION	537
CHAPTER 29. CXF	555
29.1. DEPENDENCIES	555
29.2. URI FORMAT	555

29.3. CONFIGURING OPTIONS	555
29.3.1. Configuring Component Options	555
29.3.2. Configuring Endpoint Options	556
29.4. COMPONENT OPTIONS	556
29.5. ENDPOINT OPTIONS	557
29.5.1. Path Parameters (2 parameters)	557
29.5.2. Query Parameters (35 parameters)	558
29.5.3. Descriptions of the dataformats	561
29.5.4. How to enable CXF's LoggingOutInterceptor in RAW mode	562
29.5.5. Description of relayHeaders option	563
29.5.6. Available only in POJO mode	563
29.6. CONFIGURE THE CXF ENDPOINTS WITH SPRING	565
29.7. HOW TO MAKE THE CAMEL-CXF COMPONENT USE LOG4J INSTEAD OF JAVA.UTIL.LOGGING	568
29.8. HOW TO LET CAMEL-CXF RESPONSE START WITH XML PROCESSING INSTRUCTION	568
29.9. HOW TO OVERRIDE THE CXF PRODUCER ADDRESS FROM MESSAGE HEADER	569
29.10. HOW TO CONSUME A MESSAGE FROM A CAMEL-CXF ENDPOINT IN POJO DATA FORMAT	569
29.11. HOW TO PREPARE THE MESSAGE FOR THE CAMEL-CXF ENDPOINT IN POJO DATA FORMAT	570
29.12. HOW TO DEAL WITH THE MESSAGE FOR A CAMEL-CXF ENDPOINT IN PAYLOAD DATA FORMAT	571
29.13. HOW TO GET AND SET SOAP HEADERS IN POJO MODE	572
29.14. HOW TO GET AND SET SOAP HEADERS IN PAYLOAD MODE	573
29.15. SOAP HEADERS ARE NOT AVAILABLE IN RAW MODE	574
29.16. HOW TO THROW A SOAP FAULT FROM CAMEL	574
29.17. HOW TO PROPAGATE A CAMEL-CXF ENDPOINT'S REQUEST AND RESPONSE CONTEXT	575
29.18. ATTACHMENT SUPPORT	575
29.19. STREAMING SUPPORT IN PAYLOAD MODE	578
29.20. USING THE GENERIC CXF DISPATCH MODE	579
29.21. SPRING BOOT AUTO-CONFIGURATION	579
CHAPTER 30. CXF-RS	582
30.1. DEPENDENCIES	582

52.8. EXAMPLES	944
52.9. USING THE INFINISPAN BASED IDEMPOTENT REPOSITORY	945
52.10. USING THE INFINISPAN BASED AGGREGATION REPOSITORY	946
52.11. SPRING BOOT AUTO-CONFIGURATION	947
CHAPTER 53. JACKSONXML	953
53.1. DEPENDENCIES	953
53.2. JACKSONXML OPTIONS	953
53.2.1. Using Jackson XML in Spring DSL	955
53.2.2. Excluding POJO fields from marshalling	955
53.3. INCLUDE/EXCLUDE FIELDS USING THE JSONVIEW ATTRIBUTE WITH `JACKSONXML` DATAFORMAT	955
53.4. SETTING SERIALIZATION INCLUDE OPTION	956
53.5. UNMARSHALLING FROM XML TO POJO WITH DYNAMIC CLASS NAME	956
53.6. UNMARSHALLING FROM XML TO LIST<MAP> OR LIST<POJO>	956
53.7. USING CUSTOM JACKSON MODULES	957
53.8. ENABLING OR DISABLE FEATURES USING JACKSON	957
53.9. CONVERTING MAPS TO POJO USING JACKSON	958
53.10. FORMATTED XML MARSHALLING (PRETTY-PRINTING)	958
53.11. SPRING BOOT AUTO-CONFIGURATION	959
CHAPTER 54. JAXB	961
54.1. DEPENDENCIES	961
54.2. OPTIONS	961
54.3. USING THE JAVA DSL	963
54.4. USING SPRING XML	963
54.5. MULTIPLE CONTEXT PATHS	964
54.6. PARTIAL MARSHALLING / UNMARSHALLING	964
54.7. FRAGMENT	964
54.8. IGNORING NON-XML CHARACTERS	965
54.9. WORKING WITH THE OBJECTFACTORY	965
54.10. SETTING THE ENCODING	965
54.11. CONTROLLING NAMESPACE PREFIX MAPPING	966
54.12. SCHEMA VALIDATION	966
54.13. SCHEMA LOCATION	967
54.14. MARSHAL DATA THAT IS ALREADY XML	967
54.15. SPRING BOOT AUTO-CONFIGURATION	967
CHAPTER 55. JASYPT	970
55.1. DEPENDENCIES	970
55.2. TOOLING	970
55.3. PROTECTING THE MASTER PASSWORD	971
55.4. EXAMPLE WITH JAVA DSL	971
55.5. EXAMPLE WITH SPRING XML	972
55.6. SPRING BOOT AUTO-CONFIGURATION	973
CHAPTER 56. JDBC	975
56.1. DEPENDENCIES	975
56.2. URI FORMAT	975

56.3. CONFIGURING OPTIONS	975
56.3.1. Configuring Component Options	975
56.3.2. Configuring Endpoint Options	975
56.4. COMPONENT OPTIONS	976
56.5. ENDPOINT OPTIONS	976
56.5.1. Path Parameter (1 parameter)	977
56.5.2. Query Parameters (14 parameters)	977
56.6. MESSAGE HEADERS	979
56.7. RESULT	980
56.8. GENERATED KEYS	980
56.9. USING NAMED PARAMETERS	981
56.10. SAMPLES	981
56.11. SAMPLE - POLLING THE DATABASE EVERY MINUTE	982
56.12. SAMPLE - MOVE DATA BETWEEN DATA SOURCES	982
56.13. SPRING BOOT AUTO-CONFIGURATION	982
CHAPTER 57. JIRA	984
57.1. DEPENDENCIES	984
57.2. URI FORMAT	984
57.3. CONFIGURING OPTIONS	985
57.3.1. Configuring Component Options	985
57.3.2. Configuring Endpoint Options	985
57.4. COMPONENT OPTIONS	986
57.5. ENDPOINT OPTIONS	987
57.5.1. Path Parameters (1 parameters)	987
57.5.2. Query Parameters (16 parameters)	988
57.6. CLIENT FACTORY	990
57.7. AUTHENTICATION	990
57.7.1. Basic authentication requirements:	991
57.7.2. OAuth authentication requirements:	991
57.8. JQL	991
57.9. OPERATIONS	991
57.10. ADDISSUE	992
57.11. ADDCOMMENT	992
57.12. ATTACH	992
57.13. DELETEISSUE	992
57.14. TRANSITIONISSUE	992
57.15. UPDATEISSUE	993
57.16. WATCHER	993
57.17. WATCHUPDATES (CONSUMER)	993
57.18. SPRING BOOT AUTO-CONFIGURATION	993
CHAPTER 58. JMS	996
58.1. DEPENDENCIES	996
58.2. URI FORMAT	996
58.2.1. Using ActiveMQ	997
58.2.2. Transactions and Cache Levels	997
58.2.3. Durable Subscriptions with JMS 1.1	997
58.2.3.1. Durable Subscriptions with JMS 2.0	998
58.2.4. Message Header Mapping	998
58.3. CONFIGURING OPTIONS	998
58.3.1. Configuring Component Options	998
58.3.2. Configuring Endpoint Options	999

58.4. COMPONENT OPTIONS	999
58.5. ENDPOINT OPTIONS	1018
58.5.1. Path Parameters (2 parameters)	1019
58.5.2. Query Parameters (95 parameters)	1019
58.6. SAMPLES	1037
58.6.1. Receiving from JMS	1037
58.6.2. Sending to JMS	1038
58.6.3. Using Annotations	1038
58.6.4. Spring DSL sample	1038
58.6.5. Other samples	1038
58.6.6. Using JMS as a Dead Letter Queue storing Exchange	1038
58.6.7. Using JMS as a Dead Letter Channel storing error only	1039
58.7. MESSAGE MAPPING BETWEEN JMS AND CAMEL	1039
58.7.1. Disabling auto-mapping of JMS messages	1040
58.7.2. Using a custom MessageConverter	1040
58.7.3. Controlling the mapping strategy selected	1040
58.8. MESSAGE FORMAT WHEN SENDING	1041
58.9. MESSAGE FORMAT WHEN RECEIVING	1041
58.10. ABOUT USING CAMEL TO SEND AND RECEIVE MESSAGES AND JMSREPLYTO	1042
58.10.1. JmsProducer	1043
58.10.2. JmsConsumer	1043
58.11. REUSE ENDPOINT AND SEND TO DIFFERENT DESTINATIONS COMPUTED AT RUNTIME	1044
58.12. CONFIGURING DIFFERENT JMS PROVIDERS	1045
58.12.1. Using JNDI to find the ConnectionFactory	1045
58.13. CONCURRENT CONSUMING	1045
58.13.1. Concurrent Consuming with async consumer	1045
58.14. REQUEST/REPLY OVER JMS	1046
58.14.1. Request/reply over JMS and using a shared fixed reply queue	1048
58.14.2. Request/reply over JMS and using an exclusive fixed reply queue	1048
58.15. SYNCHRONIZING CLOCKS BETWEEN SENDERS AND RECEIVERS	1049
58.16. ABOUT TIME TO LIVE	1049
58.17. ENABLING TRANSACTED CONSUMPTION	1050
58.18. USING JMSREPLYTO FOR LATE REPLIES	1050
58.19. USING A REQUEST TIMEOUT	1051
58.20. SENDING AN INONLY MESSAGE AND KEEPING THE JMSREPLYTO HEADER	1051
58.21. SETTING JMS PROVIDER OPTIONS ON THE DESTINATION	1051
58.22. SPRING BOOT AUTO-CONFIGURATION	1052
CHAPTER 59. JOLOKIA	1070
59.1. DEPENDENCIES	1070
59.2. USING JOLOKIA AGENT	1070
59.3. USING JOLOKIA RESTRICTOR	1070
59.4. IMPLEMENTING SPRING JOLOKIA CONFIGURATION	1071
59.5. USING CAMEL LOG HANDLER HOLDER CONFIGURATION	1071
59.6. USING JOLOKIA CONFIGURATION IN KUBERNETES	1071
CHAPTER 60. JPA	1073
60.1. DEPENDENCIES	1073
60.2. SENDING TO THE ENDPOINT	1073
60.3. CONSUMING FROM THE ENDPOINT	1073
60.4. URI FORMAT	1074
60.5. CONFIGURING OPTIONS	1074
60.5.1. Configuring Component Options	1074

60.5.2. Configuring Endpoint Options	1074
60.6. COMPONENT OPTIONS	1075
60.6.1. Endpoint Options	1076
60.6.1.1. Path Parameters (1 parameters)	1076
60.6.1.2. Query Parameters (44 parameters)	1076
60.7. MESSAGE HEADERS	1082
60.8. CONFIGURING ENTITYMANAGERFACTORY	1083
60.9. CONFIGURING TRANSACTIONMANAGER	1083
60.10. USING A CONSUMER WITH A NAMED QUERY	1083
60.11. USING A CONSUMER WITH A QUERY	1084
60.12. USING A CONSUMER WITH A NATIVE QUERY	1084
60.13. USING A PRODUCER WITH A NAMED QUERY	1084
60.14. USING A PRODUCER WITH A QUERY	1084
60.15. USING A PRODUCER WITH A NATIVE QUERY	1084
60.16. USING THE JPA-BASED IDEMPOTENT REPOSITORY	1085
60.17. SPRING BOOT AUTO-CONFIGURATION	1086
CHAPTER 61. JQ	1088
61.1. DEPENDENCIES	1088
61.2. JQ OPTIONS	1088
61.3. EXAMPLES	1088
61.4. MESSAGE BODY TYPES	1088
61.5. USING HEADER AS INPUT	1089
61.6. CAMEL SUPPLIED JQ FUNCTIONS	1089
61.7. SPRING BOOT AUTO-CONFIGURATION	1089
CHAPTER 62. JSLT	1090
62.1. DEPENDENCIES	1090
62.2. URI FORMAT	1090
62.3. CONFIGURING OPTIONS	1090
62.3.1. Configuring Component Options	1090
62.3.2. Configuring Endpoint Options	1090
62.4. COMPONENT OPTIONS	1091
62.4.1. Endpoint Options	1092
62.4.1.1. Path Parameters (1 parameters)	1092
62.4.1.2. Query Parameters (7 parameters)	1092
62.5. MESSAGE HEADERS	1093
62.6. PASSING VALUES TO JSLT	1094
62.7. SAMPLES	1094
62.8. SPRING BOOT AUTO-CONFIGURATION	1095
CHAPTER 63. JSON GSON	1097
63.1. DEPENDENCIES	1097
63.2. GSON OPTIONS	1097
63.3. SPRING BOOT AUTO-CONFIGURATION	1097
CHAPTER 64. JSON JACKSON	1099
64.1. DEPENDENCIES	1099
64.2. JACKSON OPTIONS	1099
64.3. USING CUSTOM OBJECTMAPPER	1104
64.4. USING JACKSON FOR AUTOMATIC TYPE CONVERSION	1104
64.5. SPRING BOOT AUTO-CONFIGURATION	1104
CHAPTER 65. JSONPATH	1108

65.1. DEPENDENCIES	1108
65.2. JSONPATH OPTIONS	1108
65.3. EXAMPLES	1109
65.4. JSONPATH SYNTAX	1110
65.4.1. Easy JSONPath Syntax	1110
65.5. SUPPORTED MESSAGE BODY TYPES	1110
65.6. SUPPRESSING EXCEPTIONS	1111
65.7. INLINE SIMPLE EXPRESSIONS	1111
65.8. JSONPATH INJECTION	1112
65.9. ENCODING DETECTION	1112
65.10. SPLIT JSON DATA INTO SUB ROWS AS JSON	1113
65.11. USING HEADER AS INPUT	1113
65.12. SPRING BOOT AUTO-CONFIGURATION	1113
CHAPTER 66. KAFKA	1115
66.1. DEPENDENCIES	1115
66.2. URI FORMAT	1115
66.3. CONFIGURING OPTIONS	1115
66.3.1. Configuring Component Options	1115
66.3.2. Configuring Endpoint Options	1115
66.4. COMPONENT OPTIONS	1116
66.5. ENDPOINT OPTIONS	1135
66.5.1. Path Parameters (1 parameters)	1135
66.5.2. Query Parameters (108 parameters)	1135
66.6. MESSAGE HEADERS	1153
66.7. USAGE	1155
66.7.1. Consumer error handling	1155
66.7.2. Consumer error handling (advanced)	1156
66.8. USING THE KAFKA IDEMPOTENT REPOSITORY	1156
66.9. USING MANUAL COMMIT WITH KAFKA CONSUMER	1159
66.10. PAUSABLE CONSUMERS	1160
66.11. KAFKA HEADERS PROPAGATION	1160
66.12. KAFKA TRANSACTION	1161
66.13. SETTING KERBEROS CONFIG FILE	1161
66.14. BATCHING CONSUMER	1162
66.14.1. Automatic Commits	1162
66.14.1.1. Handling Errors with Automatic Commits	1162
66.14.2. Manual Commits	1163
66.14.3. Dealing with long polling timeouts	1164
66.15. CUSTOM SUBSCRIPTION ADAPTERS	1164
66.16. INTEROPERABILITY	1165
66.16.1. JMS	1165
66.17. EXAMPLES	1165
66.17.1. Consuming messages from Kafka	1165
66.17.2. Producing messages to Kafka	1166
66.17.3. SSL configuration	1167
66.18. SPRING BOOT AUTO-CONFIGURATION	1168
CHAPTER 67. KAMELET	1186
67.1. DEPENDENCIES	1186
67.2. URI FORMAT	1186
67.3. CONFIGURING OPTIONS	1186
67.3.1. Configuring Component Options	1186

67.3.2. Configuring Endpoint Options	1186
67.4. COMPONENT OPTIONS	1187
67.5. ENDPOINT OPTIONS	1188
67.5.1. Path Parameters (2 parameters)	1188
67.5.2. Query Parameters (8 parameters)	1189
67.6. DISCOVERY	1190
67.7. SAMPLES	1190
67.8. SPRING BOOT AUTO-CONFIGURATION	1191
CHAPTER 68. KAMELET MAIN	1193
68.1. INITIAL CONFIGURATION	1193
68.2. AUTOMATIC DEPENDENCIES DOWNLOADING	1193
CHAPTER 69. KUBERNETES	1194
69.1. KUBERNETES COMPONENTS	1194
69.2. DEPENDENCIES	1195
69.3. USAGE	1195
69.3.1. Producer examples	1195
69.4. USING KUBERNETES CONFIGMAPS AND SECRETS	1195
69.5. SPRING BOOT AUTO-CONFIGURATION	1195
CHAPTER 70. KUBERNETES CONFIGMAP	1213
70.1. DEPENDENCIES	1213
70.2. CONFIGURING OPTIONS	1213
70.2.1. Configuring Component Options	1213
70.2.2. Configuring Endpoint Options	1213
70.3. COMPONENT OPTIONS	1214
70.4. ENDPOINT OPTIONS	1214
70.4.1. Path Parameters (1 parameters)	1214
70.4.2. Query Parameters (33 parameters)	1215
70.5. MESSAGE HEADERS	1217
70.6. SUPPORTED PRODUCER OPERATION	1219
70.7. KUBERNETES CONFIGMAPS PRODUCER EXAMPLES	1219
70.8. KUBERNETES CONFIGMAPS CONSUMER EXAMPLE	1220
70.9. USING CONFIGMAP PROPERTIES FUNCTION WITH KUBERNETES	1220
70.9.1. Using configmap with Kubernetes	1221
70.10. AUTOMATIC CAMEL CONTEXT RELOADING ON CONFIGMAPS REFRESH	1221
70.11. SPRING BOOT AUTO-CONFIGURATION	1221
CHAPTER 71. KUBERNETES CUSTOM RESOURCES	1239
71.1. DEPENDENCIES	1239
71.2. CONFIGURING OPTIONS	1239
71.2.1. Configuring Component Options	1239
71.2.2. Configuring Endpoint Options	1239
71.3. COMPONENT OPTIONS	1240
71.4. ENDPOINT OPTIONS	1240
71.4.1. Path Parameters (1 parameters)	1240
71.4.2. Query Parameters (33 parameters)	1241
71.5. MESSAGE HEADERS	1243
71.6. SUPPORTED PRODUCER OPERATION	1246
71.7. SPRING BOOT AUTO-CONFIGURATION	1246
CHAPTER 72. KUBERNETES DEPLOYMENTS	1263
72.1. DEPENDENCIES	1263

72.2. CONFIGURING OPTIONS	1263
72.2.1. Configuring Component Options	1263
72.2.2. Configuring Endpoint Options	1263
72.3. COMPONENT OPTIONS	1264
72.4. ENDPOINT OPTIONS	1264
72.4.1. Path Parameters (1 parameters)	1264
72.4.2. Query Parameters (33 parameters)	1265
72.5. MESSAGE HEADERS	1267
72.6. SUPPORTED PRODUCER OPERATION	1269
72.7. KUBERNETES DEPLOYMENTS PRODUCER EXAMPLES	1269
72.7.1. Kubernetes Deployments Consumer Example	1270
72.8. SPRING BOOT AUTO-CONFIGURATION	1270
CHAPTER 73. KUBERNETES EVENT	1288
73.1. DEPENDENCIES	1288
73.2. CONFIGURING OPTIONS	1288
73.2.1. Configuring Component Options	1288
73.2.2. Configuring Endpoint Options	1288
73.3. COMPONENT OPTIONS	1289
73.4. ENDPOINT OPTIONS	1289
73.4.1. Path Parameters (1 parameters)	1289
73.4.2. Query Parameters (33 parameters)	1290
73.5. MESSAGE HEADERS	1292
73.6. SUPPORTED PRODUCER OPERATION	1295
73.7. KUBERNETES EVENTS PRODUCER EXAMPLES	1295
73.8. KUBERNETES EVENTS CONSUMER EXAMPLE	1298
73.9. SPRING BOOT AUTO-CONFIGURATION	1298
CHAPTER 74. KUBERNETES HPA	1316
74.1. DEPENDENCIES	1316
74.2. CONFIGURING OPTIONS	1316
74.2.1. Configuring Component Options	1316
74.2.2. Configuring Endpoint Options	1316
74.3. COMPONENT OPTIONS	1317
74.4. ENDPOINT OPTIONS	1317
74.4.1. Path Parameters (1 parameters)	1317
74.4.2. Query Parameters (33 parameters)	1318
74.5. MESSAGE HEADERS	1320
74.6. SUPPORTED PRODUCER OPERATION	1322
74.7. KUBERNETES HPA PRODUCER EXAMPLES	1322
74.8. KUBERNETES HPA CONSUMER EXAMPLE	1323
74.9. SPRING BOOT AUTO-CONFIGURATION	1323
CHAPTER 75. KUBERNETES JOB	1341
75.1. DEPENDENCIES	1341
75.2. CONFIGURING OPTIONS	1341
75.2.1. Configuring Component Options	1341
75.2.2. Configuring Endpoint Options	1341
75.3. COMPONENT OPTIONS	1342
75.4. ENDPOINT OPTIONS	1342
75.4.1. Path Parameters (1 parameters)	1342
75.4.2. Query Parameters (33 parameters)	1343
75.5. MESSAGE HEADERS	1345
75.6. SUPPORTED PRODUCER OPERATION	1346

75.7. KUBERNETES JOB PRODUCER EXAMPLES	1347
75.8. SPRING BOOT AUTO-CONFIGURATION	1349
CHAPTER 76. KUBERNETES NAMESPACES	1367
76.1. DEPENDENCIES	1367
76.2. CONFIGURING OPTIONS	1367
76.2.1. Configuring Component Options	1367
76.2.2. Configuring Endpoint Options	1367
76.3. COMPONENT OPTIONS	1368
76.4. ENDPOINT OPTIONS	1368
76.4.1. Path Parameters (1 parameters)	1368
76.4.2. Query Parameters (33 parameters)	1369
76.5. MESSAGE HEADERS	1371
76.6. SUPPORTED PRODUCER OPERATION	1372
76.7. KUBERNETES NAMESPACES PRODUCER EXAMPLES	1373
76.8. KUBERNETES NAMESPACES CONSUMER EXAMPLE	1373
76.9. SPRING BOOT AUTO-CONFIGURATION	1374
CHAPTER 77. KUBERNETES NODES	1392
77.1. DEPENDENCIES	1392
77.2. CONFIGURING OPTIONS	1392
77.2.1. Configuring Component Options	1392
77.2.2. Configuring Endpoint Options	1392
77.3. COMPONENT OPTIONS	1393
77.4. ENDPOINT OPTIONS	1393
77.4.1. Path Parameters (1 parameters)	1393
77.4.2. Query Parameters (33 parameters)	1394
77.5. MESSAGE HEADERS	1396
77.6. SUPPORTED PRODUCER OPERATION	1398
77.7. KUBERNETES NODES PRODUCER EXAMPLES	1398
77.8. KUBERNETES NODES CONSUMER EXAMPLE	1399
77.9. SPRING BOOT AUTO-CONFIGURATION	1399
CHAPTER 78. KUBERNETES PERSISTENT VOLUME	1417
78.1. DEPENDENCIES	1417
78.2. CONFIGURING OPTIONS	1417
78.2.1. Configuring Component Options	1417
78.2.2. Configuring Endpoint Options	1417
78.3. COMPONENT OPTIONS	1418
78.4. ENDPOINT OPTIONS	1418
78.4.1. Path Parameters (1 parameters)	1418
78.4.2. Query Parameters (21 parameters)	1418
78.5. MESSAGE HEADERS	1420
78.6. SUPPORTED PRODUCER OPERATION	1421
78.7. KUBERNETES PERSISTENT VOLUMES PRODUCER EXAMPLES	1421
78.8. SPRING BOOT AUTO-CONFIGURATION	1422

PREFACE

MAKING OPEN SOURCE MORE INCLUSIVE

Red Hat is committed to replacing problematic language in our code, documentation, and web properties. We are beginning with these four terms: master, slave, blacklist, and whitelist. Because of the enormity of this endeavor, these changes will be implemented gradually over several upcoming releases. For more details, see [our CTO Chris Wright's message](#).

CHAPTER 1. COMPONENT STARTERS

Camel Spring Boot supports the following Camel artifacts as Spring Boot Starters:

- [Table 1.1, “Camel Components”](#)
- [Table 1.2, “Camel Data Formats”](#)
- [Table 1.3, “Camel Languages”](#)
- [Table 1.4, “Miscellaneous Extensions”](#)

NOTE

The BOM for Red Hat build of Apache Camel for Camel Spring Boot lists both supported and unsupported components. See [Component Starters](#) for the latest list of supported components.

Table 1.1. Camel Components

Component	Artifact	Description	Support on IBM Power and IBM Z
AMQP	camel-amqp-starter	Messaging with AMQP protocol using Apache QPid Client.	Yes
AWS Cloudwatch	camel-aws2-cw-starter	Sending metrics to AWS CloudWatch using AWS SDK version 2.x.	Yes
AWS DynamoDB	camel-aws2-ddb-starter	Store and retrieve data from AWS DynamoDB service using AWS SDK version 2.x.	Yes
AWS Kinesis	camel-aws2-kinesis-starter	Consume and produce records from and to AWS Kinesis Streams using AWS SDK version 2.x.	Yes
AWS Lambda	camel-aws2-lambda-starter	Manage and invoke AWS Lambda functions using AWS SDK version 2.x.	Yes
AWS S3 Storage Service	camel-aws2-s3-starter	Store and retrieve objects from AWS S3 Storage Service using AWS SDK version 2.x.	Yes

Component	Artifact	Description	Support on IBM Power and IBM Z
AWS Simple Notification System (SNS)	camel-aws2-sns-starter	Send messages to an AWS Simple Notification Topic using AWS SDK version 2.x.	Yes
AWS Simple Queue Service (SQS)	camel-aws2-sqs-starter	Send and receive messages to/from AWS SQS service using AWS SDK version 2.x.	Yes
AWS Secrets Manager	camel-aws-secrets-manager-starter	Manage secrets using AWS Secrets Manager.	Yes
Azure Key Vault	camel-azure-key-vault-starter	Manage secrets and keys in Azure Key Vault Service	Yes
Azure ServiceBus	camel-azure-servicebus-starter	Send and receive messages to/from Azure Event Bus.	Yes
Azure Storage Blob Service	camel-azure-storage-blob-starter	Store and retrieve blobs from Azure Storage Blob Service using SDK v12.	Yes
Azure Storage Queue Service	camel-azure-storage-queue-starter	The azure-storage-queue component is used for storing and retrieving the messages to/from Azure Storage Queue using Azure SDK v12.	Yes
Bean	camel-bean-starter	Invoke methods of Java beans stored in Camel registry.	Yes
Bean Validator	camel-bean-validator-starter	Validate the message body using the Java Bean Validation API.	Yes
Browse	camel-browse-starter	Inspect the messages received on endpoints supporting BrowseableEndpoint.	Yes

Component	Artifact	Description	Support on IBM Power and IBM Z
Cassandra CQL	camel-cassandraql-starter	Integrate with Cassandra 2.0 using the CQL3 API (not the Thrift API). Based on Cassandra Java Driver provided by DataStax.	Yes
CICS	camel-cics-starter	Interact with CICS® general-purpose transaction processing subsystem.	No
Control Bus	camel-controlbus-starter	Manage and monitor Camel routes.	Yes
Cron	camel-cron-starter	A generic interface for triggering events at times specified through the Unix cron syntax.	Yes
Crypto (JCE)	camel-crypto-starter	Sign and verify exchanges using the Signature Service of the Java Cryptographic Extension (JCE).	Yes
CXF	camel-cxf-soap-starter	Expose SOAP WebServices using Apache CXF or connect to external WebServices using CXF WS client.	Yes
CXF-RS	camel-cxf-rest-starter	Expose JAX-RS REST services using Apache CXF or connect to external REST services using CXF REST client.	Yes
Data Format	camel-dataformat-starter	Use a Camel Data Format as a regular Camel Component.	Yes
Dataset	camel-dataset-starter	Provide data for load and soak testing of your Camel application.	Yes

Component	Artifact	Description	Support on IBM Power and IBM Z
Direct	camel-direct-starter	Call another endpoint from the same Camel Context synchronously.	Yes
Elastic Search	camel-elasticsearch-starter	Send requests to ElasticSearch via Java Client API.	Yes
FHIR	camel-fhir-starter	Exchange information in the healthcare domain using the FHIR (Fast Healthcare Interoperability Resources) standard.	No
File	camel-file-starter	Read and write files.	Yes
Flink	camel-flink-starter	Send DataSet jobs to an Apache Flink cluster.	Yes
FTP	camel-ftp-starter	Upload and download files to/from FTP servers.	Yes
Google BigQuery	camel-google-bigquery-starter	Google BigQuery data warehouse for analytics.	Yes
Google Pubsub	camel-google-pubsub-starter	Send and receive messages to/from Google Cloud Platform PubSub Service.	Yes
Google Secret Manager	camel-google-secret-manager-starter	Manage Google Secret Manager Secrets	Yes
GraphQL	camel-graphql-starter	Send GraphQL queries and mutations to external systems.	Yes
gRPC	camel-grpc-starter	Expose gRPC endpoints and access external gRPC endpoints.	Yes
Hashicorp Vault	camel-hashicorp-starter	Manage secrets in Hashicorp Vault Service.	Yes

Component	Artifact	Description	Support on IBM Power and IBM Z
HTTP	camel-http-starter	Send requests to external HTTP servers using Apache HTTP Client 4.x.	Yes
Infinispan	camel-infinispan-starter	Read and write from/to Infinispan distributed key/value store and data grid.	No
Infinispan Embedded	camel-infinispan-embedded-starter	Read and write from/to Infinispan distributed key/value store and data grid.	Yes
JDBC	camel-jdbc-starter	Access databases through SQL and JDBC.	Yes
Jira	camel-jira-starter	Interact with JIRA issue tracker.	Yes
JMS	camel-jms-starter	Sent and receive messages to/from a JMS Queue or Topic.	Yes
Jolokia	camel-jolokia-starter	integrates the Jolokia agent configuration in Spring Boot.	Yes
JPA	camel-jpa-starter	Store and retrieve Java objects from databases using Java Persistence API (JPA).	Yes
JSLT	camel-jslt-starter	Query or transform JSON payloads using an JSLT.	Yes
Kafka	camel-kafka-starter	Sent and receive messages to/from an Apache Kafka broker.	Yes
Kamelet	camel-kamelet-starter	To call Kamelets	Yes

Component	Artifact	Description	Support on IBM Power and IBM Z
Kubernetes ConfigMap	camel-kubernetes-starter	Perform operations on Kubernetes ConfigMaps and get notified on ConfigMaps changes.	Yes
Kubernetes Custom Resources	camel-kubernetes-starter	Perform operations on Kubernetes Custom Resources and get notified on Deployment changes.	Yes
Kubernetes Deployments	camel-kubernetes-starter	Perform operations on Kubernetes Deployments and get notified on Deployment changes.	Yes
Kubernetes Event	camel-kubernetes-starter	Perform operations on Kubernetes Events and get notified on Events changes.	Yes
Kubernetes HPA	camel-kubernetes-starter	Perform operations on Kubernetes Horizontal Pod Autoscalers (HPA) and get notified on HPA changes.	Yes
Kubernetes Job	camel-kubernetes-starter	Perform operations on Kubernetes Jobs.	Yes
Kubernetes Namespaces	camel-kubernetes-starter	Perform operations on Kubernetes Namespaces and get notified on Namespace changes.	Yes
Kubernetes Nodes	camel-kubernetes-starter	Perform operations on Kubernetes Nodes and get notified on Node changes.	Yes
Kubernetes Persistent Volume	camel-kubernetes-starter	Perform operations on Kubernetes Persistent Volumes and get notified on Persistent Volume changes.	Yes

Component	Artifact	Description	Support on IBM Power and IBM Z
Kubernetes Persistent Volume Claim	camel-kubernetes-starter	Perform operations on Kubernetes Persistent Volumes Claims and get notified on Persistent Volumes Claim changes.	Yes
Kubernetes Pods	camel-kubernetes-starter	Perform operations on Kubernetes Pods and get notified on Pod changes.	Yes
Kubernetes Replication Controller	camel-kubernetes-starter	Yes Perform operations on Kubernetes Replication Controllers and get notified on Replication Controllers changes.	Yes
Kubernetes Resources Quota	camel-kubernetes-starter	Perform operations on Kubernetes Resources Quotas.	Yes
Kubernetes Secrets	camel-kubernetes-starter	Perform operations on Kubernetes Secrets.	Yes
Kubernetes Service Account	camel-kubernetes-starter	Perform operations on Kubernetes Service Accounts.	Yes
Kubernetes Services	camel-kubernetes-starter	Perform operations on Kubernetes Services and get notified on Service changes.	Yes
Kudu	camel-kudu-starter	Interact with Apache Kudu, a free and open source column-oriented data store of the Apache Hadoop ecosystem.	No
Language	camel-language-starter	Execute scripts in any of the languages supported by Camel.	Yes
LDAP	camel-ldap-starter	Perform searches on LDAP servers.	Yes

Component	Artifact	Description	Support on IBM Power and IBM Z
Log	camel-log-starter	Log messages to the underlying logging mechanism.	Yes
LRA	camel-lra-starter	Camel saga binding for Long-Running-Action framework.	Yes
Mail	camel-mail-starter	Send and receive emails using imap, pop3 and smtp protocols.	Yes
Mail Microsoft OAuth	camel-mail-microsoft-oauth-starter	Camel Mail OAuth2 Authenticator for Microsoft Exchange Online.	Yes
MapStruct	camel-mapstruct-starter	Type Conversion using Mapstruct.	Yes
Master	camel-master-starter	Have only a single consumer in a cluster consuming from a given endpoint; with automatic failover if the JVM dies.	Yes
Micrometer	camel-micrometer-starter	Collect various metrics directly from Camel routes using the Micrometer library.	Yes
Minio	camel-minio-starter	Store and retrieve objects from Minio Storage Service using Minio SDK.	Yes
MLLP	camel-mlp-starter	Communicate with external systems using the MLLP protocol.	Yes
Mock	camel-mock-starter	Test routes and mediation rules using mocks.	Yes
MongoDB	camel-mongodb-starter	Perform operations on MongoDB documents and collections.	Yes

Component	Artifact	Description	Support on IBM Power and IBM Z
MyBatis	camel-mybatis-starter	Performs a query, poll, insert, update or delete in a relational database using MyBatis.	Yes
Netty	camel-netty-starter	Socket level networking using TCP or UDP with Netty 4.x.	Yes
Observability Services	camel-observability-services	Camel Observability Services	Yes
Olingo4	camel-olingo4-starter	Communicate with OData 4.0 services using Apache Olingo OData API.	Yes
OpenSearch	camel-opensearch-starter	Send requests to OpenSearch via Java Client API.	Yes
Openshift Builds	camel-kubernetes-starter	Perform operations on OpenShift Builds.	Yes
Openshift Deployment Configs	camel-kubernetes-starter	Perform operations on Openshift Deployment Configs and get notified on Deployment Config changes.	Yes
Netty HTTP	camel-netty-http-starter	Netty HTTP server and client using the Netty 4.x.	Yes
Paho	camel-paho-starter	Communicate with MQTT message brokers using Eclipse Paho MQTT Client.	Yes
Paho MQTT 5	camel-paho-mqtt5-starter	Communicate with MQTT message brokers using Eclipse Paho MQTT v5 Client.	Yes

Component	Artifact	Description	Support on IBM Power and IBM Z
Platform HTTP	camel-platform-http-starter	Expose HTTP endpoints using the HTTP server available in the current platform.	Yes
Quartz	camel-quartz-starter	Schedule sending of messages using the Quartz 2.x scheduler.	Yes
Ref	camel-ref-starter	Route messages to an endpoint looked up dynamically by name in the Camel Registry.	Yes
REST	camel-rest-starter	Expose REST services or call external REST services.	Yes
Saga	camel-saga-starter	Execute custom actions within a route using the Saga EIP.	Yes
Salesforce	camel-salesforce-starter	Communicate with Salesforce using Java DTOs.	Yes
SAP	camel-sap-starter	Uses the SAP Java Connector (SAP JCo) library to facilitate bidirectional communication with SAP and the SAP IDoc library to facilitate the transmission of documents in the Intermediate Document (IDoc) format.	Yes
Scheduler	camel-scheduler-starter	Generate messages in specified intervals using <code>java.util.concurrent.ScheduledExecutorService</code> .	Yes
SEDA	camel-seda-starter	Asynchronously call another endpoint from any Camel Context in the same JVM.	Yes

Component	Artifact	Description	Support on IBM Power and IBM Z
Servlet	camel-servlet-starter	Serve HTTP requests by a Servlet.	Yes
Slack	camel-slack-starter	Send and receive messages to/from Slack.	Yes
SMB	camel-smb-starter	Receive files from SMB (Server Message Block) shares.	Yes
Smooks	camel-smooks-starter	Transform and bind XML as well as non-XML data, including EDI, CSV, JSON, and YAML using Smooks.	Yes
SNMP	camel-snmp-starter	Receive traps and poll SNMP (Simple Network Management Protocol) capable devices.	Yes
Splunk	camel-splunk-starter	Publish or search for events in Splunk.	No
Spring Batch	camel-spring-batch-starter	Send messages to Spring Batch for further processing.	Yes
Spring JDBC	camel-spring-jdbc-starter	Access databases through SQL and JDBC with Spring Transaction support.	Yes
Spring LDAP	camel-spring-ldap-starter	Perform searches in LDAP servers using filters as the message payload.	Yes
Spring RabbitMQ	camel-spring-rabbitmq-starter	Send and receive messages from RabbitMQ using Spring RabbitMQ client.	Yes
Spring Redis	camel-spring-redis-starter	Send and receive messages from Redis.	Yes

Component	Artifact	Description	Support on IBM Power and IBM Z
Spring Webservice	camel-spring-ws-starter	You can use this component to integrate with Spring Web Services. It offers client-side support for accessing web services and server-side support for creating your contract-first web services.	Yes
SQL	camel-sql-starter	Perform SQL queries using Spring JDBC.	Yes
SQL Stored Procedure	camel-sql-starter	Perform SQL queries as a JDBC Stored Procedures using Spring JDBC.	Yes
SSH	camel-ssh-starter	Execute commands on remote hosts using SSH.	Yes
Stub	camel-stub-starter	Stub out any physical endpoints while in development or testing.	Yes
Telegram	camel-telegram-starter	Send and receive messages acting as a Telegram Bot Telegram Bot API.	Yes
Timer	camel-timer-starter	Generate messages in specified intervals using java.util.Timer.	Yes
Validator	camel-validator-starter	Validate the payload using XML Schema and JAXP Validation.	Yes
Velocity	camel-velocity-starter	Transform messages using a Velocity template.	Yes
Vert.x HTTP Client	camel-vertx-http-starter	Send requests to external HTTP servers using Vert.x.	Yes

Component	Artifact	Description	Support on IBM Power and IBM Z
Vert.x WebSocket	camel-vertx-websocket-starter	Expose WebSocket endpoints and connect to remote WebSocket servers using Vert.x.	Yes
Webhook	camel-webhook-starter	Expose webhook endpoints to receive push notifications for other Camel components.	Yes
XJ	camel-xj-starter	Transform JSON and XML message using a XSLT.	Yes
XSLT	camel-xslt-starter	Transforms XML payload using an XSLT template.	Yes
XSLT Saxon	camel-xslt-saxon-starter	Transform XML payloads using an XSLT template using Saxon.	Yes

Table 1.2. Camel Data Formats

Component	Artifact	Description	Support on IBM Power and IBM Z
Avro	camel-avro-starter	Serialize and deserialize messages using Apache Avro binary data format.	Yes
Avro Jackson	camel-jackson-avro-starter	Marshal POJOs to Avro and back using Jackson.	Yes
Bindy	camel-bindy-starter	Marshal and unmarshal between POJOs and key-value pair (KVP) format using Camel Bindy.	Yes
BeanIO	camel-beanio-starter	Marshal and unmarshal Java beans to and from flat files (such as CSV, delimited, or fixed length formats).	Yes

Component	Artifact	Description	Support on IBM Power and IBM Z
HL7	camel-hl7-starter	Marshal and unmarshal HL7 (Health Care) model objects using the HL7 MLLP codec.	Yes
JacksonXML	camel-jacksonxml-starter	Unmarshal a XML payloads to POJOs and back using XMLMapper extension of Jackson.	Yes
JAXB	camel-jaxb-starter	Unmarshal XML payloads to POJOs and back using JAXB2 XML marshalling standard.	Yes
JSON Gson	camel-gson-starter	Marshal POJOs to JSON and back using Gson	Yes
JSON Jackson	camel-jackson-starter	Marshal POJOs to JSON and back using Jackson	Yes
Protobuf Jackson	camel-jackson-protobuf-starter	Marshal POJOs to Protobuf and back using Jackson.	Yes
SOAP	camel-soap-starter	Marshal Java objects to SOAP messages and back.	Yes
Zip File	camel-zipfile-starter	Compression and decompress streams using java.util.zip.ZipStream.	Yes

Table 1.3. Camel Languages

Language	Artifact	Description	Support on IBM Power and IBM Z
Constant	camel-core-starter	A fixed value set only once during the route startup.	Yes

Language	Artifact	Description	Support on IBM Power and IBM Z
CSimple	camel-core-starter	Evaluate a compiled simple expression.	Yes
ExchangeProperty	camel-core-starter	Gets a property from the Exchange.	Yes
File	camel-core-starter	File related capabilities for the Simple language.	Yes
Groovy	camel-groovy-starter	Evaluates a Groovy script.	Yes
Header	camel-core-starter	Gets a header from the Exchange.	Yes
JQ	camel-jq-starter	Evaluates a JQ expression against a JSON message body.	Yes
JSONPath	camel-jsonpath-starter	Evaluates a JSONPath expression against a JSON message body.	Yes
Ref	camel-core-starter	Uses an existing expression from the registry.	Yes
Simple	camel-core-starter	Evaluates a Camel simple expression.	Yes
Tokenize	camel-core-starter	Tokenize text payloads using delimiter patterns.	Yes
XML Tokenize	camel-xml-jaxp-starter	Tokenize XML payloads.	Yes
XPath	camel-xpath-starter	Evaluates an XPath expression against an XML payload.	Yes
XQuery	camel-saxon-starter	Query and/or transform XML payloads using XQuery and Saxon.	Yes

Table 1.4. Miscellaneous Extensions

Extensions	Artifact	Description	Support on IBM Power and IBM Z
Jasypt	camel-jasypt-starter	Security using Jasypt	Yes
Kamelet Main	camel-kamelet-main-starter	Main to run Kamelet standalone	Yes
Openapi Java	camel-openapi-java-starter	Rest-dsl support for using openapi doc	Yes
OpenTelemetry	camel-opentelemetry-starter	Distributed tracing using OpenTelemetry	Yes
Spring Security	camel-spring-security-starter	Security using Spring Security	Yes
YAML DSL	camel-yaml-dsl-starter	Camel DSL with YAML	Yes

CHAPTER 2. AMQP

Since Camel 1.2

Both producer and consumer are supported

The AMQP component supports the [AMQP 1.0 protocol](#) using the JMS Client API of the [Qpid](#) project.

2.1. DEPENDENCIES

When using **camel-amqp** with Red Hat build of Camel Spring Boot, add the following Maven dependency to your **pom.xml** to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-amqp-starter</artifactId>
</dependency>
```

2.2. URI FORMAT

```
amqp:[queue:]topic:]destinationName[?options]
```

2.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

2.3.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).
- directly in the Java code.

2.3.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

2.4. COMPONENT OPTIONS

The AMQP component supports 100 options, which are listed below.

Name	Description	Default	Type
clientId (common)	Sets the JMS client ID to use. Note that this value, if specified, must be unique and can only be used by a single JMS connection instance. The clientId option is compulsory with JMS 1.1 durable topic subscriptions, because the client ID is used to control which client messages have to be stored for. With JMS 2.0 clients, clientId may be omitted, which creates a 'global' subscription.		String
connectionFactory (common)	The connection factory to be use. A connection factory must be configured either on the component or endpoint.		ConnectionFactory
disableReplyTo (common)	Specifies whether Camel ignores the JMSReplyTo header in messages. If true, Camel does not send a reply back to the destination specified in the JMSReplyTo header. You can use this option if you want Camel to consume from a route and you do not want Camel to automatically send back a reply message because another component in your code handles the reply message. You can also use this option if you want to use Camel as a proxy between different message brokers and you want to route message from one system to another.	false	boolean
durableSubscriptionName (common)	The durable subscriber name for specifying durable topic subscriptions. The clientId option must be configured for a JMS 1.1 durable subscription, and may be configured for JMS 2.0, to create a private durable subscription.		String

Name	Description	Default	Type
includeAmqpAnnotations (common)	Whether to include AMQP annotations when mapping from AMQP to Camel Message. Setting this to true maps AMQP message annotations that contain a JMS_AMQP_MA_ prefix to message headers. Due to limitations in Apache Qpid JMS API, currently delivery annotations are ignored.	false	boolean
jmsMessageType (common)	Allows you to force the use of a specific javax.jms.Message implementation for sending JMS messages. Possible values are: Bytes, Map, Object, Stream, Text. By default, Camel would determine which JMS message type to use from the In body type. This option allows you to specify it. Enum values: • Bytes • Map • Object • Stream • Text		JmsMessageType
replyTo (common)	Provides an explicit ReplyTo destination (overrides any incoming value of Message.getJMSReplyTo() in consumer).		String
testConnectionOnStartup (common)	Specifies whether to test the connection on startup. This ensures that when Camel starts that all the JMS consumers have a valid connection to the JMS broker. If a connection cannot be granted then Camel throws an exception on startup. This ensures that Camel is not started with failed connections. The JMS producers is tested as well.	false	boolean

Name	Description	Default	Type
acknowledgmentModeName (consumer)	The JMS acknowledgement name, which is one of: SESSION_TRANSACTED, CLIENT_ACKNOWLEDGE, AUTO_ACKNOWLEDGE, DUPS_OK_ACKNOWLEDGE. Enum values: • SESSION_TRANSACTED • CLIENT_ACKNOWLEDGE • AUTO_ACKNOWLEDGE • DUPS_OK_ACKNOWLEDGE	AUTO_ACKNOWLEDGE	String
artemisConsumerPriority (consumer)	Consumer priorities allow you to ensure that high priority consumers receive messages while they are active. Normally, active consumers connected to a queue receive messages from it in a round-robin fashion. When consumer priorities are in use, messages are delivered round-robin if multiple active consumers exist with the same high priority. Messages will only go to lower priority consumers when the high priority consumers do not have credit available to consume the message, or those high priority consumers have declined to accept the message (for instance because it does not meet the criteria of any selectors associated with the consumer).		int
asyncConsumer (consumer)	Whether the JmsConsumer processes the Exchange asynchronously. If enabled then the JmsConsumer may pickup the next message from the JMS queue, while the previous message is being processed asynchronously (by the Asynchronous Routing Engine). This means that messages may be processed not 100% strictly in order. If disabled (as default) then the Exchange is fully processed before the JmsConsumer picks up the next message from the JMS queue. Note if transacted has been enabled, then asyncConsumer=true does not run asynchronously, as transaction must be executed synchronously (Camel 3.0 may support async transactions).	false	boolean
autoStartup (consumer)	Specifies whether the consumer container should auto-startup.	true	boolean

Name	Description	Default	Type
cacheLevel (consumer)	Sets the cache level by ID for the underlying JMS resources. See <code>cacheLevelName</code> option for more details.		int
cacheLevelName (consumer)	Sets the cache level by name for the underlying JMS resources. Possible values are: <code>CACHE_AUTO</code>, <code>CACHE_CONNECTION</code>, <code>CACHE_CONSUMER</code>, <code>CACHE_NONE</code>, and <code>CACHE_SESSION</code>. The default setting is <code>CACHE_AUTO</code>. See the Spring documentation and Transactions Cache Levels for more information. Enum values: • <code>CACHE_AUTO</code> • <code>CACHE_CONNECTION</code> • <code>CACHE_CONSUMER</code> • <code>CACHE_NONE</code> • <code>CACHE_SESSION</code>	<code>CACHE_AUTO</code>	String
concurrentConsumers (consumer)	Specifies the default number of concurrent consumers when consuming from JMS (not for request/reply over JMS). See also the <code>maxMessagesPerTask</code> option to control dynamic scaling up/down of threads. When doing request/reply over JMS then the option <code>replyToConcurrentConsumers</code> is used to control number of concurrent consumers on the reply message listener.	1	int
maxConcurrentConsumers (consumer)	Specifies the maximum number of concurrent consumers when consuming from JMS (not for request/reply over JMS). See also the <code>maxMessagesPerTask</code> option to control dynamic scaling up/down of threads. When doing request/reply over JMS then the option <code>replyToMaxConcurrentConsumers</code> is used to control number of concurrent consumers on the reply message listener.		int
replyToDeliveryPersistent (consumer)	Specifies whether to use persistent delivery by default for replies.	true	boolean

Name	Description	Default	Type
selector (consumer)	Sets the JMS selector to use.		String
subscriptionDurable (consumer)	Set whether to make the subscription durable. The durable subscription name to be used can be specified through the <code>subscriptionName</code> property. Default is false. Set this to true to register a durable subscription, typically in combination with a <code>subscriptionName</code> value (unless your message listener class name is good enough as subscription name). Only makes sense when listening to a topic (pub-sub domain), therefore this method switches the <code>pubSubDomain</code> flag as well.	false	boolean
subscriptionName (consumer)	Set the name of a subscription to create. To be applied in case of a topic (pub-sub domain) with a shared or durable subscription. The subscription name needs to be unique within this client's JMS client id, if the client ID is configured. Default is the class name of the specified message listener. Note: Only 1 concurrent consumer (which is the default of this message listener container) is allowed for each subscription, except for a shared subscription (which requires JMS 2.0).		String
subscriptionShared (consumer)	Set whether to make the subscription shared. The shared subscription name to be used can be specified through the <code>subscriptionName</code> property. Default is false. Set this to true to register a shared subscription, typically in combination with a <code>subscriptionName</code> value (unless your message listener class name is good enough as subscription name). Note that shared subscriptions may also be durable, so this flag can (and often will) be combined with <code>subscriptionDurable</code> as well. Only makes sense when listening to a topic (pub-sub domain), therefore this method switches the <code>pubSubDomain</code> flag as well. Requires a JMS 2.0 compatible message broker.	false	boolean

Name	Description	Default	Type
acceptMessagesWhileStopping (consumer (advanced))	Specifies whether the consumer accept messages while it is stopping. You may consider enabling this option, if you start and stop JMS routes at runtime, while there are still messages enqueued on the queue. If this option is false, and you stop the JMS route, then messages may be rejected, and the JMS broker would have to attempt redeliveries, which yet again may be rejected, and eventually the message may be moved at a dead letter queue on the JMS broker. To avoid this its recommended to enable this option.	false	boolean
allowReplyManagerQuickStop (consumer (advanced))	Whether the DefaultMessageListenerContainer used in the reply managers for request-reply messaging allow the DefaultMessageListenerContainer.runningAllowed flag to quick stop in case JmsConfiguration#isAcceptMessagesWhileStopping is enabled, and org.apache.camel.CamelContext is currently being stopped. This quick stop ability is enabled by default in the regular JMS consumers but to enable for reply managers you must enable this flag.	false	boolean
consumerType (consumer (advanced))	The consumer type to use, which can be one of: Simple, Default, or Custom. The consumer type determines which Spring JMS listener to use. Default will use <code>org.springframework.jms.listener.DefaultMessageListenerContainer</code>, Simple will use <code>org.springframework.jms.listener.SimpleMessageListenerContainer</code>. When Custom is specified, the <code>MessageListenerContainerFactory</code> defined by the <code>messageListenerContainerFactory</code> option will determine what <code>org.springframework.jms.listener.AbstractMessageListenerContainer</code> to use. Enum values: • Simple • Default • Custom	Default	ConsumerType

Name	Description	Default	Type
defaultTaskExecutorType (consumer (advanced))	Specifies what default TaskExecutor type to use in the DefaultMessageListenerContainer, for both consumer endpoints and the ReplyTo consumer of producer endpoints. Possible values: SimpleAsync (uses Spring's SimpleAsyncTaskExecutor) or ThreadPool (uses Spring's ThreadPoolTaskExecutor with optimal values - cached threadpool-like). If not set, it defaults to the previous behaviour, which uses a cached thread pool for consumer endpoints and SimpleAsync for reply consumers. The use of ThreadPool is recommended to reduce thread trash in elastic configurations with dynamically increasing and decreasing concurrent consumers. Enum values: • ThreadPool • SimpleAsync		DefaultTaskExecutorType
eagerLoadingOfProperties (consumer (advanced))	Enables eager loading of JMS properties and payload as soon as a message is loaded which generally is inefficient as the JMS properties may not be required but sometimes can catch early any issues with the underlying JMS provider and the use of JMS properties. See also the option eagerPoisonBody.	false	boolean
eagerPoisonBody (consumer (advanced))	If eagerLoadingOfProperties is enabled and the JMS message payload (JMS body or JMS properties) is poison (cannot be read/mapped), then set this text as the message body instead so the message can be processed (the cause of the poison are already stored as exception on the Exchange). This can be turned off by setting eagerPoisonBody=false. See also the option eagerLoadingOfProperties.	Poison JMS message due to \${exception.message}	String
exposeListenerSession (consumer (advanced))	Specifies whether the listener session should be exposed when consuming messages.	false	boolean

Name	Description	Default	Type
replyToConsumerType (consumer (advanced))	The consumer type of the reply consumer (when doing request/reply), which can be one of: Simple, Default, or Custom. The consumer type determines which Spring JMS listener to use. Default will use <code>org.springframework.jms.listener.DefaultMessageListenerContainer</code>, Simple will use <code>org.springframework.jms.listener.SimpleMessageListenerContainer</code>. When Custom is specified, the <code>MessageListenerContainerFactory</code> defined by the <code>messageListenerContainerFactory</code> option will determine what <code>org.springframework.jms.listener.AbstractMessageListenerContainer</code> to use. Enum values: • Simple • Default • Custom	Default	ConsumerType
replyToSameDestinationAllowed (consumer (advanced))	Whether a JMS consumer is allowed to send a reply message to the same destination that the consumer is using to consume from. This prevents an endless loop by consuming and sending back the same message to itself.	false	boolean
taskExecutor (consumer (advanced))	Allows you to specify a custom task executor for consuming messages.		TaskExecutor
deliveryDelay (producer)	Sets delivery delay to use for send calls for JMS. This option requires JMS 2.0 compliant broker.	-1	long
deliveryMode (producer)	Specifies the delivery mode to be used. Possible values are those defined by <code>javax.jms.DeliveryMode</code>. <code>NON_PERSISTENT</code> = 1 and <code>PERSISTENT</code> = 2. Enum values: • 1 • 2		Integer
deliveryPersistent (producer)	Specifies whether persistent delivery is used by default.	true	boolean

Name	Description	Default	Type
explicitQosEnabled (producer)	Set if the deliveryMode, priority or timeToLive qualities of service should be used when sending messages. This option is based on Spring's JmsTemplate. The deliveryMode, priority and timeToLive options are applied to the current endpoint. This contrasts with the preserveMessageQos option, which operates at message granularity, reading QoS properties exclusively from the Camel In message headers.	false	Boolean
formatDateHeadersToIso8601 (producer)	Sets whether JMS date properties should be formatted according to the ISO 8601 standard.	false	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
preserveMessageQos (producer)	Set to true, if you want to send message using the QoS settings specified on the message, instead of the QoS settings on the JMS endpoint. The following three headers are considered JMSPriority, JMSDeliveryMode, and JMSExpiration. You can provide all or only some of them. If not provided, Camel will fall back to use the values from the endpoint instead. So, when using this option, the headers override the values from the endpoint. The explicitQosEnabled option, by contrast, will only use options set on the endpoint, and not values from the message header.	false	boolean

Name	Description	Default	Type
priority (producer)	Values greater than 1 specify the message priority when sending (where 1 is the lowest priority and 9 is the highest). The <code>explicitQosEnabled</code> option must also be enabled in order for this option to have any effect. Enum values: • 1 • 2 • 3 • 4 • 5 • 6 • 7 • 8 • 9	4	int
replyToConcurrentConsumers (producer)	Specifies the default number of concurrent consumers when doing request/reply over JMS. See also the <code>maxMessagesPerTask</code> option to control dynamic scaling up/down of threads.	1	int
replyToMaxConcurrentConsumers (producer)	Specifies the maximum number of concurrent consumers when using request/reply over JMS. See also the <code>maxMessagesPerTask</code> option to control dynamic scaling up/down of threads.		int
replyToOnTimeoutMaxConcurrentConsumers (producer)	Specifies the maximum number of concurrent consumers for continue routing when timeout occurred when using request/reply over JMS.	1	int
replyToOverride (producer)	Provides an explicit <code>ReplyTo</code> destination in the JMS message, which overrides the setting of <code>replyTo</code> . It is useful if you want to forward the message to a remote Queue and receive the reply message from the <code>ReplyTo</code> destination.		String

Name	Description	Default	Type
replyToType (producer)	Allows for explicitly specifying which kind of strategy to use for replyTo queues when doing request/reply over JMS. Possible values are: Temporary, Shared, or Exclusive. By default Camel will use temporary queues. However if replyTo has been configured, then Shared is used by default. This option allows you to use exclusive queues instead of shared ones. See Camel JMS documentation for more details, and especially the notes about the implications if running in a clustered environment, and the fact that Shared reply queues has lower performance than its alternatives Temporary and Exclusive. Enum values: • Temporary • Shared • Exclusive		ReplyToType
requestTimeout (producer)	The timeout for waiting for a reply when using the InOut Exchange Pattern (in milliseconds). The default is 20 seconds. You can include the header CamelJmsRequestTimeout to override this endpoint configured timeout value, and thus have per message individual timeout values. See also the requestTimeoutCheckerInterval option.	20000	long
timeToLive (producer)	When sending messages, specifies the time-to-live of the message (in milliseconds).	-1	long
allowAdditionalHeaders (producer (advanced))	This option is used to allow additional headers which may have values that are invalid according to JMS specification. For example some message systems such as WMQ do this with header names using prefix JMS_IBM_MQMD_ containing values with byte array or other invalid types. You can specify multiple header names separated by comma, and use as suffix for wildcard matching.		String
allowNullBody (producer (advanced))	Whether to allow sending messages with no body. If this option is false and the message body is null, then an JMSEException is thrown.	true	boolean

Name	Description	Default	Type
alwaysCopyMessage (producer (advanced))	If true, Camel will always make a JMS message copy of the message when it is passed to the producer for sending. Copying the message is needed in some situations, such as when a <code>replyToDestinationSelectorName</code> is set (incidentally, Camel will set the <code>alwaysCopyMessage</code> option to true, if a <code>replyToDestinationSelectorName</code> is set).	false	boolean
correlationProperty (producer (advanced))	When using <code>InOut</code> exchange pattern use this JMS property instead of <code>JMSCorrelationID</code> JMS property to correlate messages. If set messages will be correlated solely on the value of this property <code>JMSCorrelationID</code> property will be ignored and not set by Camel.		String
disableTimeToLive (producer (advanced))	Use this option to force disabling time to live. For example when you do request/reply over JMS, then Camel will by default use the <code>requestTimeout</code> value as time to live on the message being sent. The problem is that the sender and receiver systems have to have their clocks synchronized, so they are in sync. This is not always so easy to archive. So you can use <code>disableTimeToLive=true</code> to not set a time to live value on the sent message. Then the message will not expire on the receiver system. See below in section About time to live for more details.	false	boolean
forceSendOriginalMessage (producer (advanced))	When using <code>mapJmsMessage=false</code> Camel will create a new JMS message to send to a new JMS destination if you touch the headers (get or set) during the route. Set this option to true to force Camel to send the original JMS message that was received.	false	boolean
includeSentJMSMessageID (producer (advanced))	Only applicable when sending to JMS destination using <code>InOnly</code> (eg fire and forget). Enabling this option will enrich the Camel Exchange with the actual <code>JMSMessageID</code> that was used by the JMS client when the message was sent to the JMS destination.	false	boolean

Name	Description	Default	Type
replyToCacheLevelName (producer (advanced))	Sets the cache level by name for the reply consumer when doing request/reply over JMS. This option only applies when using fixed reply queues (not temporary). Camel will by default use: <code>CACHE_CONSUMER</code> for exclusive or shared w/ <code>replyToSelectorName</code>. And <code>CACHE_SESSION</code> for shared without <code>replyToSelectorName</code>. Some JMS brokers such as IBM WebSphere may require to set the <code>replyToCacheLevelName=CACHE_NONE</code> to work. Note: If using temporary queues then <code>CACHE_NONE</code> is not allowed, and you must use a higher value such as <code>CACHE_CONSUMER</code> or <code>CACHE_SESSION</code>. Enum values: • <code>CACHE_AUTO</code> • <code>CACHE_CONNECTION</code> • <code>CACHE_CONSUMER</code> • <code>CACHE_NONE</code> • <code>CACHE_SESSION</code>		String
replyToSelectorName (producer (advanced))	Sets the JMS Selector using the fixed name to be used so you can filter out your own replies from the others when using a shared queue (that is, if you are not using a temporary reply queue).		String
streamMessageTypeEnabled (producer (advanced))	Sets whether <code>StreamMessage</code> type is enabled or not. Message payloads of streaming kind such as files, <code>InputStream</code> , etc will either be sent as <code>BytesMessage</code> or <code>StreamMessage</code> . This option controls which kind will be used. By default <code>BytesMessage</code> is used which enforces the entire message payload to be read into memory. By enabling this option the message payload is read into memory in chunks and each chunk is then written to the <code>StreamMessage</code> until no more data.	false	boolean
allowAutoWiredConnectionFactory (advanced)	Whether to auto-discover <code>ConnectionFactory</code> from the registry, if no connection factory has been configured. If only one instance of <code>ConnectionFactory</code> is found then it will be used. This is enabled by default.	true	boolean

Name	Description	Default	Type
allowAutoWiredDestinationResolver (advanced)	Whether to auto-discover DestinationResolver from the registry, if no destination resolver has been configured. If only one instance of DestinationResolver is found then it will be used. This is enabled by default.	true	boolean
allowSerializedHeaders (advanced)	Controls whether or not to include serialized headers. Applies only when transferExchange is true. This requires that the objects are serializable. Camel will exclude any non-serializable objects and log it at WARN level.	false	boolean
artemisStreamingEnabled (advanced)	Whether optimizing for Apache Artemis streaming mode. This can reduce memory overhead when using Artemis with JMS StreamMessage types. This option must only be enabled if Apache Artemis is being used.	false	boolean
asyncStartListener (advanced)	Whether to startup the JmsConsumer message listener asynchronously, when starting a route. For example if a JmsConsumer cannot get a connection to a remote JMS broker, then it may block while retrying and/or failover. This will cause Camel to block while starting routes. By setting this option to true, you will let routes startup, while the JmsConsumer connects to the JMS broker using a dedicated thread in asynchronous mode. If this option is used, then beware that if the connection could not be established, then an exception is logged at WARN level, and the consumer will not be able to receive messages; You can then restart the route to retry.	false	boolean
asyncStopListener (advanced)	Whether to stop the JmsConsumer message listener asynchronously, when stopping a route.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
configuration (advanced)	To use a shared JMS configuration.		JmsConfiguration

Name	Description	Default	Type
destinationResolver (advanced)	A pluggable <code>org.springframework.jms.support.destination.DestinationResolver</code> that allows you to use your own resolver (for example, to lookup the real destination in a JNDI registry).		<code>DestinationResolver</code>
errorHandler (advanced)	Specifies a <code>org.springframework.util.ErrorHandler</code> to be invoked in case of any uncaught exceptions thrown while processing a <code>Message</code> . By default these exceptions will be logged at the <code>WARN</code> level, if no <code>errorHandler</code> has been configured. You can configure logging level and whether stack traces should be logged using <code>errorHandlerLoggingLevel</code> and <code>errorHandlerLogStackTrace</code> options. This makes it much easier to configure, than having to code a custom <code>ErrorHandler</code> .		<code>ErrorHandler</code>
exceptionListener (advanced)	Specifies the JMS Exception Listener that is to be notified of any underlying JMS exceptions.		<code>ExceptionListener</code>
idleConsumerLimit (advanced)	Specify the limit for the number of consumers that are allowed to be idle at any given time.	1	int
idleTaskExecutionLimit (advanced)	Specifies the limit for idle executions of a receive task, not having received any message within its execution. If this limit is reached, the task will shut down and leave receiving to other executing tasks (in the case of dynamic scheduling; see the <code>maxConcurrentConsumers</code> setting). There is additional doc available from Spring.	1	int
includeAllJMSXProperties (advanced)	Whether to include all <code>JMSXxxx</code> properties when mapping from JMS to Camel <code>Message</code> . Setting this to <code>true</code> will include properties such as <code>JMSXAppID</code> , and <code>JMSXUserID</code> etc. Note: If you are using a custom <code>headerFilterStrategy</code> then this option does not apply.	false	boolean

Name	Description	Default	Type
jmsKeyFormatStrategy (advanced)	Pluggable strategy for encoding and decoding JMS keys so they can be compliant with the JMS specification. Camel provides two implementations out of the box: default and passthrough. The default strategy will safely marshal dots and hyphens (. and -). The passthrough strategy leaves the key as is. Can be used for JMS brokers which do not care whether JMS header keys contain illegal characters. You can provide your own implementation of the <code>org.apache.camel.component.jms.JmsKeyFormatStrategy</code> and refer to it using the <code>#</code> notation. Enum values: • default • passthrough		JmsKeyFormatStrategy
mapJmsMessage (advanced)	Specifies whether Camel should auto map the received JMS message to a suited payload type, such as <code>javax.jms.TextMessage</code> to a <code>String</code> etc.	true	boolean
maxMessagesPerTask (advanced)	The number of messages per task. -1 is unlimited. If you use a range for concurrent consumers (eg min max), then this option can be used to set a value to eg 100 to control how fast the consumers will shrink when less work is required.	-1	int
messageConverter (advanced)	To use a custom Spring <code>org.springframework.jms.support.converter.MessageConverter</code> so you can be in control how to map to/from a <code>javax.jms.Message</code> .		MessageConverter
messageCreatedStrategy (advanced)	To use the given <code>MessageCreatedStrategy</code> which are invoked when Camel creates new instances of <code>javax.jms.Message</code> objects when Camel is sending a JMS message.		MessageCreatedStrategy
messageIdEnabled (advanced)	When sending, specifies whether message IDs should be added. This is just an hint to the JMS broker. If the JMS provider accepts this hint, these messages must have the message ID set to null; if the provider ignores the hint, the message ID must be set to its normal unique value.	true	boolean

Name	Description	Default	Type
messageListenerContainerFactory (advanced)	Registry ID of the MessageListenerContainerFactory used to determine what <code>org.springframework.jms.listener.AbstractMessageListenerContainer</code> to use to consume messages. Setting this will automatically set <code>consumerType</code> to Custom.		MessageListenerContainerFactory
messageTimestampEnabled (advanced)	Specifies whether timestamps should be enabled by default on sending messages. This is just an hint to the JMS broker. If the JMS provider accepts this hint, these messages must have the timestamp set to zero; if the provider ignores the hint the timestamp must be set to its normal value.	true	boolean
pubSubNoLocal (advanced)	Specifies whether to inhibit the delivery of messages published by its own connection.	false	boolean
queueBrowseStrategy (advanced)	To use a custom QueueBrowseStrategy when browsing queues.		QueueBrowseStrategy
receiveTimeout (advanced)	The timeout for receiving messages (in milliseconds).	1000	long
recoveryInterval (advanced)	Specifies the interval between recovery attempts, i.e. when a connection is being refreshed, in milliseconds. The default is 5000 ms, that is, 5 seconds.	5000	long
requestTimeoutCheckerInterval (advanced)	Configures how often Camel should check for timed out Exchanges when doing request/reply over JMS. By default Camel checks once per second. But if you must react faster when a timeout occurs, then you can lower this interval, to check more frequently. The timeout is determined by the option <code>requestTimeout</code> .	1000	long
synchronous (advanced)	Sets whether synchronous processing should be strictly used.	false	boolean

Name	Description	Default	Type
transferException (advanced)	If enabled and you are using Request Reply messaging (InOut) and an Exchange failed on the consumer side, then the caused Exception will be send back in response as a javax.jms.ObjectMessage. If the client is Camel, the returned Exception is rethrown. This allows you to use Camel JMS as a bridge in your routing - for example, using persistent queues to enable robust routing. Notice that if you also have transferExchange enabled, this option takes precedence. The caught exception is required to be serializable. The original Exception on the consumer side can be wrapped in an outer exception such as org.apache.camel.RuntimeCamelException when returned to the producer. Use this with caution as the data is using Java Object serialization and requires the received to be able to deserialize the data at Class level, which forces a strong coupling between the producers and consumer!.	false	boolean
transferExchange (advanced)	You can transfer the exchange over the wire instead of just the body and headers. The following fields are transferred: In body, Out body, Fault body, In headers, Out headers, Fault headers, exchange properties, exchange exception. This requires that the objects are serializable. Camel will exclude any non-serializable objects and log it at WARN level. You must enable this option on both the producer and consumer side, so Camel knows the payloads is an Exchange and not a regular payload. Use this with caution as the data is using Java Object serialization and requires the receiver to be able to deserialize the data at Class level, which forces a strong coupling between the producers and consumers having to use compatible Camel versions!.	false	boolean
useMessageIDAsCorrelationID (advanced)	Specifies whether JMSMessageID should always be used as JMSCorrelationID for InOut messages.	false	boolean
waitForProvisionCorrelationToBeUpdatedCounter (advanced)	Number of times to wait for provisional correlation id to be updated to the actual correlation id when doing request/reply over JMS and when the option useMessageIDAsCorrelationID is enabled.	50	int
waitForProvisionCorrelationToBeUpdatedThreadSleepingTime (advanced)	Interval in millis to sleep each time while waiting for provisional correlation id to be updated.	100	long

Name	Description	Default	Type
headerFilterStrategy (filter)	To use a custom <code>org.apache.camel.spi.HeaderFilterStrategy</code> to filter header to and from Camel message.		HeaderFilterStrategy
errorHandlerLoggingLevel (logging)	Allows to configure the default errorHandler logging level for logging uncaught exceptions. Enum values: • TRACE • DEBUG • INFO • WARN • ERROR • OFF	WARN	LoggingLevel
errorHandlerLogStackTrace (logging)	Allows to control whether stacktraces should be logged or not, by the default errorHandler.	true	boolean
password (security)	Password to use with the ConnectionFactory. You can also configure username/password directly on the ConnectionFactory.		String
username (security)	Username to use with the ConnectionFactory. You can also configure username/password directly on the ConnectionFactory.		String
transacted (transaction)	Specifies whether to use transacted mode.	false	boolean

Name	Description	Default	Type
transactedInOut (transaction)	Specifies whether InOut operations (request reply) default to using transacted mode. If this flag is set to true, then Spring JmsTemplate will have sessionTransacted set to true, and the acknowledgeMode as transacted on the JmsTemplate used for InOut operations. Note from Spring JMS: that within a JTA transaction, the parameters passed to createQueue, createTopic methods are not taken into account. Depending on the Java EE transaction context, the container makes its own decisions on these values. Analogously, these parameters are not taken into account within a locally managed transaction either, since Spring JMS operates on an existing JMS Session in this case. Setting this flag to true will use a short local JMS transaction when running outside of a managed transaction, and a synchronized local JMS transaction in case of a managed transaction (other than an XA transaction) being present. This has the effect of a local JMS transaction being managed alongside the main transaction (which might be a native JDBC transaction), with the JMS transaction committing right after the main transaction.	false	boolean
lazyCreateTransactionManager (transaction advanced))	If true, Camel will create a JmsTransactionManager, if there is no transactionManager injected when option transacted=true.	true	boolean
transactionManager (transaction advanced))	The Spring transaction manager to use.		PlatformTransactionManager
transactionName (transaction advanced))	The name of the transaction to use.		String
transactionTimeout (transaction advanced))	The timeout value of the transaction (in seconds), if using transacted mode.	-1	int

2.5. ENDPOINT OPTIONS

The AMQP endpoint is configured using URI syntax:

```
amqp:destinationType:destinationName
```

with the following path and query parameters:

2.5.1. Path Parameters (2 parameters)

Name	Description	Default	Type
destinationType (common)	The kind of destination to use. Enum values: • queue • topic • temp-queue • temp-topic	queue	String
destinationName (common)	Required Name of the queue or topic to use as destination.		String

2.5.2. Query Parameters (96 parameters)

Name	Description	Default	Type
clientId (common)	Sets the JMS client ID to use. Note that this value, if specified, must be unique and can only be used by a single JMS connection instance. It is typically only required for durable topic subscriptions with JMS 1.1. The clientId option is compulsory with JMS 1.1 durable topic subscriptions, because the client ID is used to control which client messages have to be stored for. With JMS 2.0 clients, clientId may be omitted, which creates a 'global' subscription.		String
connectionFactory (common)	The connection factory to be use. A connection factory must be configured either on the component or endpoint.		ConnectionFactory
disableReplyTo (common)	Specifies whether Camel ignores the JMSReplyTo header in messages. If true, Camel does not send a reply back to the destination specified in the JMSReplyTo header. You can use this option if you want Camel to consume from a route and you do not want Camel to automatically send back a reply message because another component in your code handles the reply message. You can also use this option if you want to use Camel as a proxy between different message brokers and you want to route message from one system to another.	false	boolean

Name	Description	Default	Type
durableSubscriptionName (common)	The durable subscriber name for specifying durable topic subscriptions. The clientId option must be configured for a JMS 1.1 durable subscription, and may be configured for JMS 2.0, to create a private durable subscription.		String
jmsMessageType (common)	Allows you to force the use of a specific javax.jms.Message implementation for sending JMS messages. Possible values are: Bytes, Map, Object, Stream, Text. By default, Camel would determine which JMS message type to use from the In body type. This option allows you to specify it. Enum values: • Bytes • Map • Object • Stream • Text		JmsMessageType
replyTo (common)	Provides an explicit ReplyTo destination (overrides any incoming value of Message.getJMSReplyTo() in consumer).		String
testConnectionOnStartup (common)	Specifies whether to test the connection on startup. This ensures that when Camel starts that all the JMS consumers have a valid connection to the JMS broker. If a connection cannot be granted then Camel throws an exception on startup. This ensures that Camel is not started with failed connections. The JMS producers is tested as well.	false	boolean

Name	Description	Default	Type
acknowledgmentModeName (consumer)	The JMS acknowledgement name, which is one of: SESSION_TRANSACTED, CLIENT_ACKNOWLEDGE, AUTO_ACKNOWLEDGE, DUPS_OK_ACKNOWLEDGE. Enum values: • SESSION_TRANSACTED • CLIENT_ACKNOWLEDGE • AUTO_ACKNOWLEDGE • DUPS_OK_ACKNOWLEDGE	AUTO_ACKNOWLEDGE	String
artemisConsumerPriority (consumer)	Consumer priorities allow you to ensure that high priority consumers receive messages while they are active. Normally, active consumers connected to a queue receive messages from it in a round-robin fashion. When consumer priorities are in use, messages are delivered round-robin if multiple active consumers exist with the same high priority. Messages will only go to lower priority consumers when the high priority consumers do not have credit available to consume the message, or those high priority consumers have declined to accept the message (for instance because it does not meet the criteria of any selectors associated with the consumer).		int
asyncConsumer (consumer)	Whether the JmsConsumer processes the Exchange asynchronously. If enabled then the JmsConsumer may pickup the next message from the JMS queue, while the previous message is being processed asynchronously (by the Asynchronous Routing Engine). This means that messages may be processed not 100% strictly in order. If disabled (as default) then the Exchange is fully processed before the JmsConsumer picks up the next message from the JMS queue. Note if transacted has been enabled, then asyncConsumer=true does not run asynchronously, as transaction must be executed synchronously (Camel 3.0 may support async transactions).	false	boolean
autoStartup (consumer)	Specifies whether the consumer container should auto-startup.	true	boolean

Name	Description	Default	Type
cacheLevel (consumer)	Sets the cache level by ID for the underlying JMS resources. See <code>cacheLevelName</code> option for more details.		int
cacheLevelName (consumer)	Sets the cache level by name for the underlying JMS resources. Possible values are: <code>CACHE_AUTO</code>, <code>CACHE_CONNECTION</code>, <code>CACHE_CONSUMER</code>, <code>CACHE_NONE</code>, and <code>CACHE_SESSION</code>. The default setting is <code>CACHE_AUTO</code>. See the Spring documentation and Transactions Cache Levels for more information. Enum values: ● <code>CACHE_AUTO</code> ● <code>CACHE_CONNECTION</code> ● <code>CACHE_CONSUMER</code> ● <code>CACHE_NONE</code> ● <code>CACHE_SESSION</code>	<code>CACHE_AUTO</code>	String
concurrentConsumers (consumer)	Specifies the default number of concurrent consumers when consuming from JMS (not for request/reply over JMS). See also the <code>maxMessagesPerTask</code> option to control dynamic scaling up/down of threads. When doing request/reply over JMS then the option <code>replyToConcurrentConsumers</code> is used to control number of concurrent consumers on the reply message listener.	1	int
maxConcurrentConsumers (consumer)	Specifies the maximum number of concurrent consumers when consuming from JMS (not for request/reply over JMS). See also the <code>maxMessagesPerTask</code> option to control dynamic scaling up/down of threads. When doing request/reply over JMS then the option <code>replyToMaxConcurrentConsumers</code> is used to control number of concurrent consumers on the reply message listener.		int
replyToDeliveryPersistent (consumer)	Specifies whether to use persistent delivery by default for replies.	true	boolean
selector (consumer)	Sets the JMS selector to use.		String

Name	Description	Default	Type
subscriptionDurable (consumer)	Set whether to make the subscription durable. The durable subscription name to be used can be specified through the <code>subscriptionName</code> property. Default is false. Set this to true to register a durable subscription, typically in combination with a <code>subscriptionName</code> value (unless your message listener class name is good enough as subscription name). Only makes sense when listening to a topic (pub-sub domain), therefore this method switches the <code>pubSubDomain</code> flag as well.	false	boolean
subscriptionName (consumer)	Set the name of a subscription to create. To be applied in case of a topic (pub-sub domain) with a shared or durable subscription. The subscription name needs to be unique within this client's JMS client id, if the client ID is configured. Default is the class name of the specified message listener. Note: Only 1 concurrent consumer (which is the default of this message listener container) is allowed for each subscription, except for a shared subscription (which requires JMS 2.0).		String
subscriptionShared (consumer)	Set whether to make the subscription shared. The shared subscription name to be used can be specified through the <code>subscriptionName</code> property. Default is false. Set this to true to register a shared subscription, typically in combination with a <code>subscriptionName</code> value (unless your message listener class name is good enough as subscription name). Note that shared subscriptions may also be durable, so this flag can (and often will) be combined with <code>subscriptionDurable</code> as well. Only makes sense when listening to a topic (pub-sub domain), therefore this method switches the <code>pubSubDomain</code> flag as well. Requires a JMS 2.0 compatible message broker.	false	boolean
acceptMessagesWhileStopping (consumer (advanced))	Specifies whether the consumer accept messages while it is stopping. You may consider enabling this option, if you start and stop JMS routes at runtime, while there are still messages enqueued on the queue. If this option is false, and you stop the JMS route, then messages may be rejected, and the JMS broker would have to attempt redeliveries, which yet again may be rejected, and eventually the message may be moved at a dead letter queue on the JMS broker. To avoid this its recommended to enable this option.	false	boolean

Name	Description	Default	Type
allowReplyManagerQuickStop (consumer (advanced))	Whether the DefaultMessageListenerContainer used in the reply managers for request-reply messaging allow the DefaultMessageListenerContainer.runningAllowed flag to quick stop in case JmsConfiguration#isAcceptMessagesWhileStopping is enabled, and org.apache.camel.CamelContext is currently being stopped. This quick stop ability is enabled by default in the regular JMS consumers but to enable for reply managers you must enable this flag.	false	boolean
consumerType (consumer (advanced))	The consumer type to use, which can be one of: Simple, Default, or Custom. The consumer type determines which Spring JMS listener to use. Default will use org.springframework.jms.listener.DefaultMessageListenerContainer, Simple will use org.springframework.jms.listener.SimpleMessageListenerContainer. When Custom is specified, the MessageListenerContainerFactory defined by the messageListenerContainerFactory option will determine what org.springframework.jms.listener.AbstractMessageListenerContainer to use. Enum values: • Simple • Default • Custom	Default	ConsumerType

Name	Description	Default	Type
defaultTaskExecutorType (consumer (advanced))	Specifies what default TaskExecutor type to use in the DefaultMessageListenerContainer, for both consumer endpoints and the ReplyTo consumer of producer endpoints. Possible values: SimpleAsync (uses Spring's SimpleAsyncTaskExecutor) or ThreadPool (uses Spring's ThreadPoolTaskExecutor with optimal values - cached threadpool-like). If not set, it defaults to the previous behaviour, which uses a cached thread pool for consumer endpoints and SimpleAsync for reply consumers. The use of ThreadPool is recommended to reduce thread trash in elastic configurations with dynamically increasing and decreasing concurrent consumers. Enum values: • ThreadPool • SimpleAsync		DefaultTaskExecutorType
eagerLoadingOfProperties (consumer (advanced))	Enables eager loading of JMS properties and payload as soon as a message is loaded which generally is inefficient as the JMS properties may not be required but sometimes can catch early any issues with the underlying JMS provider and the use of JMS properties. See also the option eagerPoisonBody.	false	boolean
eagerPoisonBody (consumer (advanced))	If eagerLoadingOfProperties is enabled and the JMS message payload (JMS body or JMS properties) is poison (cannot be read/mapped), then set this text as the message body instead so the message can be processed (the cause of the poison are already stored as exception on the Exchange). This can be turned off by setting eagerPoisonBody=false. See also the option eagerLoadingOfProperties.	Poison JMS message due to \${exception.message}	String
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler

Name	Description	Default	Type
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: ● InOnly ● InOut ● InOptionalOut		ExchangePattern
exposeListenerSession (consumer (advanced))	Specifies whether the listener session should be exposed when consuming messages.	false	boolean
replyToConsumerType (consumer (advanced))	The consumer type of the reply consumer (when doing request/reply), which can be one of: Simple, Default, or Custom. The consumer type determines which Spring JMS listener to use. Default will use <code>org.springframework.jms.listener.DefaultMessageListenerContainer</code>, Simple will use <code>org.springframework.jms.listener.SimpleMessageListenerContainer</code>. When Custom is specified, the <code>MessageListenerContainerFactory</code> defined by the <code>messageListenerContainerFactory</code> option will determine what <code>org.springframework.jms.listener.AbstractMessageListenerContainer</code> to use. Enum values: ● Simple ● Default ● Custom	Default	ConsumerType
replyToSameDestinationAllowed (consumer (advanced))	Whether a JMS consumer is allowed to send a reply message to the same destination that the consumer is using to consume from. This prevents an endless loop by consuming and sending back the same message to itself.	false	boolean
taskExecutor (consumer (advanced))	Allows you to specify a custom task executor for consuming messages.		TaskExecutor

Name	Description	Default	Type
deliveryDelay (producer)	Sets delivery delay to use for send calls for JMS. This option requires JMS 2.0 compliant broker.	-1	long
deliveryMode (producer)	Specifies the delivery mode to be used. Possible values are those defined by <code>javax.jms.DeliveryMode</code> . <code>NON_PERSISTENT</code> = 1 and <code>PERSISTENT</code> = 2. Enum values: • 1 • 2		Integer
deliveryPersistent (producer)	Specifies whether persistent delivery is used by default.	true	boolean
explicitQosEnabled (producer)	Set if the <code>deliveryMode</code> , <code>priority</code> or <code>timeToLive</code> qualities of service should be used when sending messages. This option is based on Spring's <code>JmsTemplate</code> . The <code>deliveryMode</code> , <code>priority</code> and <code>timeToLive</code> options are applied to the current endpoint. This contrasts with the <code>preserveMessageQos</code> option, which operates at message granularity, reading QoS properties exclusively from the Camel In message headers.	false	Boolean
formatDateHeadersToIso8601 (producer)	Sets whether JMS date properties should be formatted according to the ISO 8601 standard.	false	boolean
preserveMessageQos (producer)	Set to true, if you want to send message using the QoS settings specified on the message, instead of the QoS settings on the JMS endpoint. The following three headers are considered <code>JMSPriority</code> , <code>JMSDeliveryMode</code> , and <code>JMSExpiration</code> . You can provide all or only some of them. If not provided, Camel will fall back to use the values from the endpoint instead. So, when using this option, the headers override the values from the endpoint. The <code>explicitQosEnabled</code> option, by contrast, will only use options set on the endpoint, and not values from the message header.	false	boolean

Name	Description	Default	Type
priority (producer)	Values greater than 1 specify the message priority when sending (where 1 is the lowest priority and 9 is the highest). The <code>explicitQosEnabled</code> option must also be enabled in order for this option to have any effect. Enum values: • 1 • 2 • 3 • 4 • 5 • 6 • 7 • 8 • 9	4	int
replyToConcurrentConsumers (producer)	Specifies the default number of concurrent consumers when doing request/reply over JMS. See also the <code>maxMessagesPerTask</code> option to control dynamic scaling up/down of threads.	1	int
replyToMaxConcurrentConsumers (producer)	Specifies the maximum number of concurrent consumers when using request/reply over JMS. See also the <code>maxMessagesPerTask</code> option to control dynamic scaling up/down of threads.		int
replyToOnTimeoutMaxConcurrentConsumers (producer)	Specifies the maximum number of concurrent consumers for continue routing when timeout occurred when using request/reply over JMS.	1	int
replyToOverride (producer)	Provides an explicit <code>ReplyTo</code> destination in the JMS message, which overrides the setting of <code>replyTo</code> . It is useful if you want to forward the message to a remote Queue and receive the reply message from the <code>ReplyTo</code> destination.		String

Name	Description	Default	Type
replyToType (producer)	Allows for explicitly specifying which kind of strategy to use for replyTo queues when doing request/reply over JMS. Possible values are: Temporary, Shared, or Exclusive. By default Camel will use temporary queues. However if replyTo has been configured, then Shared is used by default. This option allows you to use exclusive queues instead of shared ones. See Camel JMS documentation for more details, and especially the notes about the implications if running in a clustered environment, and the fact that Shared reply queues has lower performance than its alternatives Temporary and Exclusive. Enum values: • Temporary • Shared • Exclusive		ReplyToType
requestTimeout (producer)	The timeout for waiting for a reply when using the InOut Exchange Pattern (in milliseconds). The default is 20 seconds. You can include the header CamelJmsRequestTimeout to override this endpoint configured timeout value, and thus have per message individual timeout values. See also the requestTimeoutCheckerInterval option.	20000	long
timeToLive (producer)	When sending messages, specifies the time-to-live of the message (in milliseconds).	-1	long
allowAdditionalHeaders (producer (advanced))	This option is used to allow additional headers which may have values that are invalid according to JMS specification. For example some message systems such as WMQ do this with header names using prefix JMS_IBM_MQMD_ containing values with byte array or other invalid types. You can specify multiple header names separated by comma, and use as suffix for wildcard matching.		String
allowNullBody (producer (advanced))	Whether to allow sending messages with no body. If this option is false and the message body is null, then an JMSEException is thrown.	true	boolean

Name	Description	Default	Type
alwaysCopyMessage (producer (advanced))	If true, Camel will always make a JMS message copy of the message when it is passed to the producer for sending. Copying the message is needed in some situations, such as when a <code>replyToDestinationSelectorName</code> is set (incidentally, Camel will set the <code>alwaysCopyMessage</code> option to true, if a <code>replyToDestinationSelectorName</code> is set).	false	boolean
correlationProperty (producer (advanced))	When using <code>InOut</code> exchange pattern use this JMS property instead of <code>JMSCorrelationID</code> JMS property to correlate messages. If set messages will be correlated solely on the value of this property <code>JMSCorrelationID</code> property will be ignored and not set by Camel.		String
disableTimeToLive (producer (advanced))	Use this option to force disabling time to live. For example when you do request/reply over JMS, then Camel will by default use the <code>requestTimeout</code> value as time to live on the message being sent. The problem is that the sender and receiver systems have to have their clocks synchronized, so they are in sync. This is not always so easy to archive. So you can use <code>disableTimeToLive=true</code> to not set a time to live value on the sent message. Then the message will not expire on the receiver system. See below in section About time to live for more details.	false	boolean
forceSendOriginalMessage (producer (advanced))	When using <code>mapJmsMessage=false</code> Camel will create a new JMS message to send to a new JMS destination if you touch the headers (get or set) during the route. Set this option to true to force Camel to send the original JMS message that was received.	false	boolean
includeSentJMSMessageID (producer (advanced))	Only applicable when sending to JMS destination using <code>InOnly</code> (eg fire and forget). Enabling this option will enrich the Camel Exchange with the actual <code>JMSMessageID</code> that was used by the JMS client when the message was sent to the JMS destination.	false	boolean

Name	Description	Default	Type
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
replyToCacheLevelName (producer (advanced))	Sets the cache level by name for the reply consumer when doing request/reply over JMS. This option only applies when using fixed reply queues (not temporary). Camel will by default use: <code>CACHE_CONSUMER</code> for exclusive or shared w/ <code>replyToSelectorName</code>. And <code>CACHE_SESSION</code> for shared without <code>replyToSelectorName</code>. Some JMS brokers such as IBM WebSphere may require to set the <code>replyToCacheLevelName=CACHE_NONE</code> to work. Note: If using temporary queues then <code>CACHE_NONE</code> is not allowed, and you must use a higher value such as <code>CACHE_CONSUMER</code> or <code>CACHE_SESSION</code>. Enum values: ● <code>CACHE_AUTO</code> ● <code>CACHE_CONNECTION</code> ● <code>CACHE_CONSUMER</code> ● <code>CACHE_NONE</code> ● <code>CACHE_SESSION</code>		String
replyToDestinationSelectorName (producer (advanced))	Sets the JMS Selector using the fixed name to be used so you can filter out your own replies from the others when using a shared queue (that is, if you are not using a temporary reply queue).		String

Name	Description	Default	Type
streamMessageTypeEnabled (producer (advanced))	Sets whether StreamMessage type is enabled or not. Message payloads of streaming kind such as files, InputStream, etc will either be sent as BytesMessage or StreamMessage. This option controls which kind will be used. By default BytesMessage is used which enforces the entire message payload to be read into memory. By enabling this option the message payload is read into memory in chunks and each chunk is then written to the StreamMessage until no more data.	false	boolean
allowSerializedHeaders (advanced)	Controls whether or not to include serialized headers. Applies only when transferExchange is true. This requires that the objects are serializable. Camel will exclude any non-serializable objects and log it at WARN level.	false	boolean
artemisStreamingEnabled (advanced)	Whether optimizing for Apache Artemis streaming mode. This can reduce memory overhead when using Artemis with JMS StreamMessage types. This option must only be enabled if Apache Artemis is being used.	false	boolean
asyncStartListener (advanced)	Whether to startup the JmsConsumer message listener asynchronously, when starting a route. For example if a JmsConsumer cannot get a connection to a remote JMS broker, then it may block while retrying and/or failover. This will cause Camel to block while starting routes. By setting this option to true, you will let routes startup, while the JmsConsumer connects to the JMS broker using a dedicated thread in asynchronous mode. If this option is used, then beware that if the connection could not be established, then an exception is logged at WARN level, and the consumer will not be able to receive messages; You can then restart the route to retry.	false	boolean
asyncStopListener (advanced)	Whether to stop the JmsConsumer message listener asynchronously, when stopping a route.	false	boolean
destinationResolver (advanced)	A pluggable org.springframework.jms.support.destination.DestinationResolver that allows you to use your own resolver (for example, to lookup the real destination in a JNDI registry).		DestinationResolver

Name	Description	Default	Type
errorHandler (advanced)	Specifies a <code>org.springframework.util.ErrorHandler</code> to be invoked in case of any uncaught exceptions thrown while processing a Message. By default these exceptions will be logged at the WARN level, if no errorHandler has been configured. You can configure logging level and whether stack traces should be logged using <code>errorHandlerLoggingLevel</code> and <code>errorHandlerLogStackTrace</code> options. This makes it much easier to configure, than having to code a custom errorHandler.		ErrorHandler
exceptionListener (advanced)	Specifies the JMS Exception Listener that is to be notified of any underlying JMS exceptions.		ExceptionListener
headerFilterStrategy (advanced)	To use a custom HeaderFilterStrategy to filter header to and from Camel message.		HeaderFilterStrategy
idleConsumerLimit (advanced)	Specify the limit for the number of consumers that are allowed to be idle at any given time.	1	int
idleTaskExecutionLimit (advanced)	Specifies the limit for idle executions of a receive task, not having received any message within its execution. If this limit is reached, the task will shut down and leave receiving to other executing tasks (in the case of dynamic scheduling; see the <code>maxConcurrentConsumers</code> setting). There is additional doc available from Spring.	1	int
includeAllJMSXProperties (advanced)	Whether to include all JMSxxxx properties when mapping from JMS to Camel Message. Setting this to true will include properties such as <code>JMSXAppID</code> , and <code>JMSXUserID</code> etc. Note: If you are using a custom headerFilterStrategy then this option does not apply.	false	boolean

Name	Description	Default	Type
jmsKeyFormatStrategy (advanced)	Pluggable strategy for encoding and decoding JMS keys so they can be compliant with the JMS specification. Camel provides two implementations out of the box: default and passthrough. The default strategy will safely marshal dots and hyphens (. and -). The passthrough strategy leaves the key as is. Can be used for JMS brokers which do not care whether JMS header keys contain illegal characters. You can provide your own implementation of the <code>org.apache.camel.component.jms.JmsKeyFormatStrategy</code> and refer to it using the <code>#</code> notation. Enum values: • default • passthrough		JmsKeyFormatStrategy
mapJmsMessage (advanced)	Specifies whether Camel should auto map the received JMS message to a suited payload type, such as <code>javax.jms.TextMessage</code> to a <code>String</code> etc.	true	boolean
maxMessagesPerTask (advanced)	The number of messages per task. -1 is unlimited. If you use a range for concurrent consumers (eg min max), then this option can be used to set a value to eg 100 to control how fast the consumers will shrink when less work is required.	-1	int
messageConverter (advanced)	To use a custom Spring <code>org.springframework.jms.support.converter.MessageConverter</code> so you can be in control how to map to/from a <code>javax.jms.Message</code> .		MessageConverter
messageCreatedStrategy (advanced)	To use the given <code>MessageCreatedStrategy</code> which are invoked when Camel creates new instances of <code>javax.jms.Message</code> objects when Camel is sending a JMS message.		MessageCreatedStrategy
messageIdEnabled (advanced)	When sending, specifies whether message IDs should be added. This is just an hint to the JMS broker. If the JMS provider accepts this hint, these messages must have the message ID set to null; if the provider ignores the hint, the message ID must be set to its normal unique value.	true	boolean

Name	Description	Default	Type
messageListenerContainerFactory (advanced)	Registry ID of the MessageListenerContainerFactory used to determine what <code>org.springframework.jms.listener.AbstractMessageListenerContainer</code> to use to consume messages. Setting this will automatically set <code>consumerType</code> to Custom.		MessageListenerContainerFactory
messageTimestampEnabled (advanced)	Specifies whether timestamps should be enabled by default on sending messages. This is just an hint to the JMS broker. If the JMS provider accepts this hint, these messages must have the timestamp set to zero; if the provider ignores the hint the timestamp must be set to its normal value.	true	boolean
pubSubNoLocal (advanced)	Specifies whether to inhibit the delivery of messages published by its own connection.	false	boolean
receiveTimeout (advanced)	The timeout for receiving messages (in milliseconds).	1000	long
recoveryInterval (advanced)	Specifies the interval between recovery attempts, i.e. when a connection is being refreshed, in milliseconds. The default is 5000 ms, that is, 5 seconds.	5000	long
requestTimeoutCheckerInterval (advanced)	Configures how often Camel should check for timed out Exchanges when doing request/reply over JMS. By default Camel checks once per second. But if you must react faster when a timeout occurs, then you can lower this interval, to check more frequently. The timeout is determined by the option <code>requestTimeout</code> .	1000	long
synchronous (advanced)	Sets whether synchronous processing should be strictly used.	false	boolean

Name	Description	Default	Type
transferException (advanced)	If enabled and you are using Request Reply messaging (InOut) and an Exchange failed on the consumer side, then the caused Exception will be send back in response as a javax.jms.ObjectMessage. If the client is Camel, the returned Exception is rethrown. This allows you to use Camel JMS as a bridge in your routing - for example, using persistent queues to enable robust routing. Notice that if you also have transferExchange enabled, this option takes precedence. The caught exception is required to be serializable. The original Exception on the consumer side can be wrapped in an outer exception such as org.apache.camel.RuntimeCamelException when returned to the producer. Use this with caution as the data is using Java Object serialization and requires the received to be able to deserialize the data at Class level, which forces a strong coupling between the producers and consumer!.	false	boolean
transferExchange (advanced)	You can transfer the exchange over the wire instead of just the body and headers. The following fields are transferred: In body, Out body, Fault body, In headers, Out headers, Fault headers, exchange properties, exchange exception. This requires that the objects are serializable. Camel will exclude any non-serializable objects and log it at WARN level. You must enable this option on both the producer and consumer side, so Camel knows the payloads is an Exchange and not a regular payload. Use this with caution as the data is using Java Object serialization and requires the receiver to be able to deserialize the data at Class level, which forces a strong coupling between the producers and consumers having to use compatible Camel versions!.	false	boolean
useMessageIDAsCorrelationID (advanced)	Specifies whether JMSMessageID should always be used as JMSCorrelationID for InOut messages.	false	boolean
waitForProvisionCorrelationToBeUpdatedCounter (advanced)	Number of times to wait for provisional correlation id to be updated to the actual correlation id when doing request/reply over JMS and when the option useMessageIDAsCorrelationID is enabled.	50	int
waitForProvisionCorrelationToBeUpdatedThreadSleepingTime (advanced)	Interval in millis to sleep each time while waiting for provisional correlation id to be updated.	100	long

Name	Description	Default	Type
errorHandlerLoggingLevel (logging)	Allows to configure the default errorHandler logging level for logging uncaught exceptions. Enum values: ● TRACE ● DEBUG ● INFO ● WARN ● ERROR ● OFF	WARN	LogLevel
errorHandlerLogStackTrace (logging)	Allows to control whether stacktraces should be logged or not, by the default errorHandler.	true	boolean
password (security)	Password to use with the ConnectionFactory. You can also configure username/password directly on the ConnectionFactory.		String
username (security)	Username to use with the ConnectionFactory. You can also configure username/password directly on the ConnectionFactory.		String
transacted (transaction)	Specifies whether to use transacted mode.	false	boolean

Name	Description	Default	Type
transactedInOut (transaction)	Specifies whether InOut operations (request reply) default to using transacted mode. If this flag is set to true, then Spring JmsTemplate will have sessionTransacted set to true, and the acknowledgeMode as transacted on the JmsTemplate used for InOut operations. Note from Spring JMS: that within a JTA transaction, the parameters passed to createQueue, createTopic methods are not taken into account. Depending on the Java EE transaction context, the container makes its own decisions on these values. Analogously, these parameters are not taken into account within a locally managed transaction either, since Spring JMS operates on an existing JMS Session in this case. Setting this flag to true will use a short local JMS transaction when running outside of a managed transaction, and a synchronized local JMS transaction in case of a managed transaction (other than an XA transaction) being present. This has the effect of a local JMS transaction being managed alongside the main transaction (which might be a native JDBC transaction), with the JMS transaction committing right after the main transaction.	false	boolean
lazyCreateTransactionManager (transaction (advanced))	If true, Camel will create a JmsTransactionManager, if there is no transactionManager injected when option transacted=true.	true	boolean
transactionManager (transaction (advanced))	The Spring transaction manager to use.		PlatformTransactionManager
transactionName (transaction (advanced))	The name of the transaction to use.		String
transactionTimeout (transaction (advanced))	The timeout value of the transaction (in seconds), if using transacted mode.	-1	int

2.6. USAGE

As AMQP component is inherited from JMS component, the usage of the former is almost identical to the latter:

Using AMQP component

```
// Consuming from AMQP queue
from("amqp:queue:incoming").
  to(...);

// Sending message to the AMQP topic
from(...).
  to("amqp:topic:notify");
```

2.7. CONFIGURING AMQP COMPONENT

Creating AMQP 1.0 component

```
AMQPComponent amqp = AMQPComponent.amqpComponent("amqp://localhost:5672");

AMQPComponent authorizedAmqp = AMQPComponent.amqpComponent("amqp://localhost:5672",
  "user", "password");
```

You can also add an instance of **org.apache.camel.component.amqp.AMQPConnectionDetails** to the registry in order to automatically configure the AMQP component. For example for Spring Boot you just have to define bean:

AMQP connection details auto-configuration

```
@Bean
AMQPConnectionDetails amqpConnection() {
    return new AMQPConnectionDetails("amqp://localhost:5672");
}

@Bean
AMQPConnectionDetails securedAmqpConnection() {
    return new AMQPConnectionDetails("amqp://localhost:5672", "username", "password");
}
```

Likewise, you can also use CDI producer methods when using Camel-CDI

AMQP connection details auto-configuration for CDI

```
@Produces
AMQPConnectionDetails amqpConnection() {
    return new AMQPConnectionDetails("amqp://localhost:5672");
}
```

You can also rely on the to read the AMQP connection details. Factory method **AMQPConnectionDetails.discoverAMQP()** attempts to read Camel properties in a Kubernetes-like convention, just as demonstrated on the snippet below:

AMQP connection details auto-configuration

```
export AMQP_SERVICE_HOST = "mybroker.com"
export AMQP_SERVICE_PORT = "6666"
export AMQP_SERVICE_USERNAME = "username"
export AMQP_SERVICE_PASSWORD = "password"
```

```
...
@Bean
AMQPConnectionDetails amqpConnection() {
    return AMQPConnectionDetails.discoverAMQP();
}
```

Enabling AMQP specific options

If you, for example, need to enable **amqp.traceFrames** you can do that by appending the option to your URI, like the following example:

```
AMQPComponent amqp = AMQPComponent.amqpComponent("amqp://localhost:5672?
amqp.traceFrames=true");
```

For reference refer [QPID JMS client configuration](#).

2.8. USING TOPICS

To have using topics working with **camel-amqp** you need to configure the component to use **topic://** as topic prefix, as shown below:

```
<bean id="amqp" class="org.apache.camel.component.amqp.AmqpComponent">
  <property name="connectionFactory">
    <bean class="org.apache.qpid.jms.JmsConnectionFactory" factory-method="createFromURL">
      <property name="remoteURI" value="amqp://localhost:5672" />
      <property name="topicPrefix" value="topic://" /> <!-- only necessary when connecting to
ActiveMQ over AMQP 1.0 -->
    </bean>
  </property>
</bean>
```

Keep in mind that both **AMQPComponent#amqpComponent()** methods and **AMQPConnectionDetails** pre-configure the component with the topic prefix, so you don't have to configure it explicitly.

2.9. SPRING BOOT AUTO-CONFIGURATION

The component supports 101 options, which are listed below.

Name	Description	Default	Type
------	-------------	---------	------

Name	Description	Default	Type
camel.component.amqp.accept-messages-while-stopping	Specifies whether the consumer accept messages while it is stopping. You may consider enabling this option, if you start and stop JMS routes at runtime, while there are still messages enqueued on the queue. If this option is false, and you stop the JMS route, then messages may be rejected, and the JMS broker would have to attempt redeliveries, which yet again may be rejected, and eventually the message may be moved at a dead letter queue on the JMS broker. To avoid this its recommended to enable this option.	false	Boolean
camel.component.amqp.acknowledgement-mode-name	The JMS acknowledgement name, which is one of: SESSION_TRANSACTED, CLIENT_ACKNOWLEDGE, AUTO_ACKNOWLEDGE, DUPS_OK_ACKNOWLEDGE.	AUTO_ACKNOWLEDGE	String
camel.component.amqp.allow-additional-headers	This option is used to allow additional headers which may have values that are invalid according to JMS specification. For example some message systems such as WMQ do this with header names using prefix JMS_IBM_MQMD_ containing values with byte array or other invalid types. You can specify multiple header names separated by comma, and use as suffix for wildcard matching.		String
camel.component.amqp.allow-auto-wired-connection-factory	Whether to auto-discover ConnectionFactory from the registry, if no connection factory has been configured. If only one instance of ConnectionFactory is found then it will be used. This is enabled by default.	true	Boolean
camel.component.amqp.allow-auto-wired-destination-resolver	Whether to auto-discover DestinationResolver from the registry, if no destination resolver has been configured. If only one instance of DestinationResolver is found then it will be used. This is enabled by default.	true	Boolean
camel.component.amqp.allow-null-body	Whether to allow sending messages with no body. If this option is false and the message body is null, then an JMSEException is thrown.	true	Boolean

Name	Description	Default	Type
camel.component.amqp.allow-reply-manager-quick-stop	Whether the DefaultMessageListenerContainer used in the reply managers for request-reply messaging allow the DefaultMessageListenerContainer.runningAllowed flag to quick stop in case JmsConfiguration#isAcceptMessagesWhileStopping is enabled, and org.apache.camel.CamelContext is currently being stopped. This quick stop ability is enabled by default in the regular JMS consumers but to enable for reply managers you must enable this flag.	false	Boolean
camel.component.amqp.allow-serialized-headers	Controls whether or not to include serialized headers. Applies only when transferExchange is true. This requires that the objects are serializable. Camel will exclude any non-serializable objects and log it at WARN level.	false	Boolean
camel.component.amqp.always-copy-message	If true, Camel will always make a JMS message copy of the message when it is passed to the producer for sending. Copying the message is needed in some situations, such as when a replyToDestinationSelectorName is set (incidentally, Camel will set the alwaysCopyMessage option to true, if a replyToDestinationSelectorName is set).	false	Boolean
camel.component.amqp.artemis-consumer-priority	Consumer priorities allow you to ensure that high priority consumers receive messages while they are active. Normally, active consumers connected to a queue receive messages from it in a round-robin fashion. When consumer priorities are in use, messages are delivered round-robin if multiple active consumers exist with the same high priority. Messages will only going to lower priority consumers when the high priority consumers do not have credit available to consume the message, or those high priority consumers have declined to accept the message (for instance because it does not meet the criteria of any selectors associated with the consumer).		Integer
camel.component.amqp.artemis-streaming-enabled	Whether optimizing for Apache Artemis streaming mode. This can reduce memory overhead when using Artemis with JMS StreamMessage types. This option must only be enabled if Apache Artemis is being used.	false	Boolean

Name	Description	Default	Type
camel.component.amqp.async-consumer	Whether the JmsConsumer processes the Exchange asynchronously. If enabled then the JmsConsumer may pickup the next message from the JMS queue, while the previous message is being processed asynchronously (by the Asynchronous Routing Engine). This means that messages may be processed not 100% strictly in order. If disabled (as default) then the Exchange is fully processed before the JmsConsumer picks up the next message from the JMS queue. Note if transacted has been enabled, then <code>asyncConsumer=true</code> does not run asynchronously, as transaction must be executed synchronously (Camel 3.0 may support async transactions).	false	Boolean
camel.component.amqp.async-start-listener	Whether to startup the JmsConsumer message listener asynchronously, when starting a route. For example if a JmsConsumer cannot get a connection to a remote JMS broker, then it may block while retrying and/or failover. This will cause Camel to block while starting routes. By setting this option to true, you will let routes startup, while the JmsConsumer connects to the JMS broker using a dedicated thread in asynchronous mode. If this option is used, then beware that if the connection could not be established, then an exception is logged at WARN level, and the consumer will not be able to receive messages; You can then restart the route to retry.	false	Boolean
camel.component.amqp.async-stop-listener	Whether to stop the JmsConsumer message listener asynchronously, when stopping a route.	false	Boolean
camel.component.amqp.auto-startup	Specifies whether the consumer container should auto-startup.	true	Boolean
camel.component.amqp.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.amqp.cache-level	Sets the cache level by ID for the underlying JMS resources. See <code>cacheLevelName</code> option for more details.		Integer
camel.component.amqp.cache-level-name	Sets the cache level by name for the underlying JMS resources. Possible values are: <code>CACHE_AUTO</code> , <code>CACHE_CONNECTION</code> , <code>CACHE_CONSUMER</code> , <code>CACHE_NONE</code> , and <code>CACHE_SESSION</code> . The default setting is <code>CACHE_AUTO</code> . See the Spring documentation and Transactions Cache Levels for more information.	<code>CACHE_AUTO</code>	String
camel.component.amqp.client-id	Sets the JMS client ID to use. Note that this value, if specified, must be unique and can only be used by a single JMS connection instance. It is typically only required for durable topic subscriptions with JMS 1.1.		String
camel.component.amqp.concurrent-consumers	Specifies the default number of concurrent consumers when consuming from JMS (not for request/reply over JMS). See also the <code>maxMessagesPerTask</code> option to control dynamic scaling up/down of threads. When doing request/reply over JMS then the option <code>replyToConcurrentConsumers</code> is used to control number of concurrent consumers on the reply message listener.	1	Integer
camel.component.amqp.configuration	To use a shared JMS configuration. The option is a <code>org.apache.camel.component.jms.JmsConfiguration</code> type.		<code>JmsConfiguration</code>
camel.component.amqp.connection-factory	The connection factory to be use. A connection factory must be configured either on the component or endpoint. The option is a <code>javax.jms.ConnectionFactory</code> type.		<code>ConnectionFactory</code>
camel.component.amqp.consumer-type	The consumer type to use, which can be one of: Simple, Default, or Custom. The consumer type determines which Spring JMS listener to use. Default will use <code>org.springframework.jms.listener.DefaultMessageListenerContainer</code> , Simple will use <code>org.springframework.jms.listener.SimpleMessageListenerContainer</code> . When Custom is specified, the <code>MessageListenerContainerFactory</code> defined by the <code>messageListenerContainerFactory</code> option will determine what <code>org.springframework.jms.listener.AbstractMessageListenerContainer</code> to use.		<code>ConsumerType</code>

Name	Description	Default	Type
camel.component.amqp.correlation-property	When using InOut exchange pattern use this JMS property instead of JMSCorrelationID JMS property to correlate messages. If set messages will be correlated solely on the value of this property JMSCorrelationID property will be ignored and not set by Camel.		String
camel.component.amqp.default-task-executor-type	Specifies what default TaskExecutor type to use in the DefaultMessageListenerContainer, for both consumer endpoints and the ReplyTo consumer of producer endpoints. Possible values: SimpleAsync (uses Spring's SimpleAsyncTaskExecutor) or ThreadPool (uses Spring's ThreadPoolTaskExecutor with optimal values - cached threadpool-like). If not set, it defaults to the previous behaviour, which uses a cached thread pool for consumer endpoints and SimpleAsync for reply consumers. The use of ThreadPool is recommended to reduce thread trash in elastic configurations with dynamically increasing and decreasing concurrent consumers.		DefaultTaskExecutorType
camel.component.amqp.delivery-delay	Sets delivery delay to use for send calls for JMS. This option requires JMS 2.0 compliant broker.	-1	Long
camel.component.amqp.delivery-mode	Specifies the delivery mode to be used. Possible values are those defined by javax.jms.DeliveryMode. NON_PERSISTENT = 1 and PERSISTENT = 2.		Integer
camel.component.amqp.delivery-persistent	Specifies whether persistent delivery is used by default.	true	Boolean
camel.component.amqp.destination-resolver	A pluggable org.springframework.jms.support.destination.DestinationResolver that allows you to use your own resolver (for example, to lookup the real destination in a JNDI registry). The option is a org.springframework.jms.support.destination.DestinationResolver type.		DestinationResolver

Name	Description	Default	Type
camel.component.amqp.disable-reply-to	Specifies whether Camel ignores the JMSReplyTo header in messages. If true, Camel does not send a reply back to the destination specified in the JMSReplyTo header. You can use this option if you want Camel to consume from a route and you do not want Camel to automatically send back a reply message because another component in your code handles the reply message. You can also use this option if you want to use Camel as a proxy between different message brokers and you want to route message from one system to another.	false	Boolean
camel.component.amqp.disable-time-to-live	Use this option to force disabling time to live. For example when you do request/reply over JMS, then Camel will by default use the requestTimeout value as time to live on the message being sent. The problem is that the sender and receiver systems have to have their clocks synchronized, so they are in sync. This is not always so easy to archive. So you can use disableTimeToLive=true to not set a time to live value on the sent message. Then the message will not expire on the receiver system. See below in section About time to live for more details.	false	Boolean
camel.component.amqp.durable-subscription-name	The durable subscriber name for specifying durable topic subscriptions. The clientId option must be configured as well.		String
camel.component.amqp.eager-loading-of-properties	Enables eager loading of JMS properties and payload as soon as a message is loaded which generally is inefficient as the JMS properties may not be required but sometimes can catch early any issues with the underlying JMS provider and the use of JMS properties. See also the option eagerPoisonBody.	false	Boolean
camel.component.amqp.eager-poison-body	If eagerLoadingOfProperties is enabled and the JMS message payload (JMS body or JMS properties) is poison (cannot be read/mapped), then set this text as the message body instead so the message can be processed (the cause of the poison are already stored as exception on the Exchange). This can be turned off by setting eagerPoisonBody=false. See also the option eagerLoadingOfProperties.	Poison JMS message due to \${exception.message}	String
camel.component.amqp.enabled	Whether to enable auto configuration of the amqp component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.amqp.error-handler	Specifies a <code>org.springframework.util.ErrorHandler</code> to be invoked in case of any uncaught exceptions thrown while processing a <code>Message</code> . By default these exceptions will be logged at the <code>WARN</code> level, if no <code>ErrorHandler</code> has been configured. You can configure logging level and whether stack traces should be logged using <code>errorHandlerLoggingLevel</code> and <code>errorHandlerLogStackTrace</code> options. This makes it much easier to configure, than having to code a custom <code>ErrorHandler</code> . The option is a <code>org.springframework.util.ErrorHandler</code> type.		<code>ErrorHandler</code>
camel.component.amqp.error-handler-log-stack-trace	Allows to control whether stacktraces should be logged or not, by the default <code>ErrorHandler</code> .	<code>true</code>	<code>Boolean</code>
camel.component.amqp.error-handler-logging-level	Allows to configure the default <code>ErrorHandler</code> logging level for logging uncaught exceptions.		<code>LoggingLevel</code>
camel.component.amqp.exception-listener	Specifies the <code>JMS Exception Listener</code> that is to be notified of any underlying <code>JMS</code> exceptions. The option is a <code>javax.jms.ExceptionListener</code> type.		<code>ExceptionListener</code>
camel.component.amqp.explicit-qos-enabled	Set if the <code>deliveryMode</code> , <code>priority</code> or <code>timeToLive</code> qualities of service should be used when sending messages. This option is based on Spring's <code>JmsTemplate</code> . The <code>deliveryMode</code> , <code>priority</code> and <code>timeToLive</code> options are applied to the current endpoint. This contrasts with the <code>preserveMessageQos</code> option, which operates at message granularity, reading <code>QoS</code> properties exclusively from the Camel In message headers.	<code>false</code>	<code>Boolean</code>
camel.component.amqp.expose-listener-session	Specifies whether the listener session should be exposed when consuming messages.	<code>false</code>	<code>Boolean</code>
camel.component.amqp.force-send-original-message	When using <code>mapJmsMessage=false</code> Camel will create a new <code>JMS</code> message to send to a new <code>JMS</code> destination if you touch the headers (get or set) during the route. Set this option to <code>true</code> to force Camel to send the original <code>JMS</code> message that was received.	<code>false</code>	<code>Boolean</code>

Name	Description	Default	Type
camel.component.amqp.format-date-headers-to-iso8601	Sets whether JMS date properties should be formatted according to the ISO 8601 standard.	false	Boolean
camel.component.amqp.header-filter-strategy	To use a custom <code>org.apache.camel.spi.HeaderFilterStrategy</code> to filter header to and from Camel message. The option is a <code>org.apache.camel.spi.HeaderFilterStrategy</code> type.		HeaderFilterStrategy
camel.component.amqp.idle-consumer-limit	Specify the limit for the number of consumers that are allowed to be idle at any given time.	1	Integer
camel.component.amqp.idle-task-execution-limit	Specifies the limit for idle executions of a receive task, not having received any message within its execution. If this limit is reached, the task will shut down and leave receiving to other executing tasks (in the case of dynamic scheduling; see the <code>maxConcurrentConsumers</code> setting). There is additional doc available from Spring.	1	Integer
camel.component.amqp.include-all-jmsx-properties	Whether to include all JMSXxxx properties when mapping from JMS to Camel Message. Setting this to true will include properties such as JMSXAppID, and JMSXUserID etc. Note: If you are using a custom <code>headerFilterStrategy</code> then this option does not apply.	false	Boolean
camel.component.amqp.include-amqp-annotations	Whether to include AMQP annotations when mapping from AMQP to Camel Message. Setting this to true maps AMQP message annotations that contain a <code>JMS_AMQP_MA_</code> prefix to message headers. Due to limitations in Apache Qpid JMS API, currently delivery annotations are ignored.	false	Boolean
camel.component.amqp.include-sent-jms-message-id	Only applicable when sending to JMS destination using <code>InOnly</code> (eg fire and forget). Enabling this option will enrich the Camel Exchange with the actual <code>JMSMessageID</code> that was used by the JMS client when the message was sent to the JMS destination.	false	Boolean

Name	Description	Default	Type
camel.component.amqp.jms-key-format-strategy	Pluggable strategy for encoding and decoding JMS keys so they can be compliant with the JMS specification. Camel provides two implementations out of the box: default and passthrough. The default strategy will safely marshal dots and hyphens (. and -). The passthrough strategy leaves the key as is. Can be used for JMS brokers which do not care whether JMS header keys contain illegal characters. You can provide your own implementation of the <code>org.apache.camel.component.jms.JmsKeyFormatStrategy</code> and refer to it using the <code>#</code> notation.		JmsKeyFormatStrategy
camel.component.amqp.jms-message-type	Allows you to force the use of a specific <code>javax.jms.Message</code> implementation for sending JMS messages. Possible values are: Bytes, Map, Object, Stream, Text. By default, Camel would determine which JMS message type to use from the In body type. This option allows you to specify it.		JmsMessageType
camel.component.amqp.lazy-create-transaction-manager	If true, Camel will create a <code>JmsTransactionManager</code> , if there is no <code>transactionManager</code> injected when option <code>transacted=true</code> .	true	Boolean
camel.component.amqp.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.amqp.map-jms-message	Specifies whether Camel should auto map the received JMS message to a suited payload type, such as <code>javax.jms.TextMessage</code> to a String etc.	true	Boolean

Name	Description	Default	Type
camel.component.amqp.max-concurrent-consumers	Specifies the maximum number of concurrent consumers when consuming from JMS (not for request/reply over JMS). See also the <code>maxMessagesPerTask</code> option to control dynamic scaling up/down of threads. When doing request/reply over JMS then the option <code>replyToMaxConcurrentConsumers</code> is used to control number of concurrent consumers on the reply message listener.		Integer
camel.component.amqp.max-messages-per-task	The number of messages per task. -1 is unlimited. If you use a range for concurrent consumers (eg min max), then this option can be used to set a value to eg 100 to control how fast the consumers will shrink when less work is required.	-1	Integer
camel.component.amqp.message-converter	To use a custom Spring <code>org.springframework.jms.support.converter.MessageConverter</code> so you can be in control how to map to/from a <code>javax.jms.Message</code> . The option is a <code>org.springframework.jms.support.converter.MessageConverter</code> type.		<code>MessageConverter</code>
camel.component.amqp.message-created-strategy	To use the given <code>MessageCreatedStrategy</code> which are invoked when Camel creates new instances of <code>javax.jms.Message</code> objects when Camel is sending a JMS message. The option is a <code>org.apache.camel.component.jms.MessageCreatedStrategy</code> type.		<code>MessageCreatedStrategy</code>
camel.component.amqp.message-id-enabled	When sending, specifies whether message IDs should be added. This is just an hint to the JMS broker. If the JMS provider accepts this hint, these messages must have the message ID set to null; if the provider ignores the hint, the message ID must be set to its normal unique value.	true	Boolean
camel.component.amqp.message-listener-container-factory	Registry ID of the <code>MessageListenerContainerFactory</code> used to determine what <code>org.springframework.jms.listener.AbstractMessageListenerContainer</code> to use to consume messages. Setting this will automatically set <code>consumerType</code> to Custom. The option is a <code>org.apache.camel.component.jms.MessageListenerContainerFactory</code> type.		<code>MessageListenerContainerFactory</code>

Name	Description	Default	Type
camel.component.amqp.message-timestamp-enabled	Specifies whether timestamps should be enabled by default on sending messages. This is just an hint to the JMS broker. If the JMS provider accepts this hint, these messages must have the timestamp set to zero; if the provider ignores the hint the timestamp must be set to its normal value.	true	Boolean
camel.component.amqp.password	Password to use with the ConnectionFactory. You can also configure username/password directly on the ConnectionFactory.		String
camel.component.amqp.preserve-message-qos	Set to true, if you want to send message using the QoS settings specified on the message, instead of the QoS settings on the JMS endpoint. The following three headers are considered JMSPriority, JMSDeliveryMode, and JMSExpiration. You can provide all or only some of them. If not provided, Camel will fall back to use the values from the endpoint instead. So, when using this option, the headers override the values from the endpoint. The explicitQosEnabled option, by contrast, will only use options set on the endpoint, and not values from the message header.	false	Boolean
camel.component.amqp.priority	Values greater than 1 specify the message priority when sending (where 1 is the lowest priority and 9 is the highest). The explicitQosEnabled option must also be enabled in order for this option to have any effect.	4	Integer
camel.component.amqp.pub-sub-no-local	Specifies whether to inhibit the delivery of messages published by its own connection.	false	Boolean
camel.component.amqp.queue-browse-strategy	To use a custom QueueBrowseStrategy when browsing queues. The option is a org.apache.camel.component.jms.QueueBrowseStrategy type.		QueueBrowseStrategy
camel.component.amqp.receive-timeout	The timeout for receiving messages (in milliseconds). The option is a long type.	1000	Long
camel.component.amqp.recovery-interval	Specifies the interval between recovery attempts, i.e. when a connection is being refreshed, in milliseconds. The default is 5000 ms, that is, 5 seconds. The option is a long type.	5000	Long

Name	Description	Default	Type
camel.component.amqp.reply-to	Provides an explicit ReplyTo destination (overrides any incoming value of <code>Message.getJMSReplyTo()</code> in consumer).		String
camel.component.amqp.reply-to-cache-level-name	Sets the cache level by name for the reply consumer when doing request/reply over JMS. This option only applies when using fixed reply queues (not temporary). Camel will by default use: <code>CACHE_CONSUMER</code> for exclusive or shared w/ <code>replyToSelectorName</code> . And <code>CACHE_SESSION</code> for shared without <code>replyToSelectorName</code> . Some JMS brokers such as IBM WebSphere may require to set the <code>replyToCacheLevelName=CACHE_NONE</code> to work. Note: If using temporary queues then <code>CACHE_NONE</code> is not allowed, and you must use a higher value such as <code>CACHE_CONSUMER</code> or <code>CACHE_SESSION</code> .		String
camel.component.amqp.reply-to-concurrent-consumers	Specifies the default number of concurrent consumers when doing request/reply over JMS. See also the <code>maxMessagesPerTask</code> option to control dynamic scaling up/down of threads.	1	Integer
camel.component.amqp.reply-to-consumer-type	The consumer type of the reply consumer (when doing request/reply), which can be one of: Simple, Default, or Custom. The consumer type determines which Spring JMS listener to use. Default will use <code>org.springframework.jms.listener.DefaultMessageListenerContainer</code> , Simple will use <code>org.springframework.jms.listener.SimpleMessageListenerContainer</code> . When Custom is specified, the <code>MessageListenerContainerFactory</code> defined by the <code>messageListenerContainerFactory</code> option will determine what <code>org.springframework.jms.listener.AbstractMessageListenerContainer</code> to use.		ConsumerType
camel.component.amqp.reply-to-delivery-persistent	Specifies whether to use persistent delivery by default for replies.	true	Boolean
camel.component.amqp.reply-to-destination-selector-name	Sets the JMS Selector using the fixed name to be used so you can filter out your own replies from the others when using a shared queue (that is, if you are not using a temporary reply queue).		String

Name	Description	Default	Type
camel.component.amqp.reply-to-max-concurrent-consumers	Specifies the maximum number of concurrent consumers when using request/reply over JMS. See also the <code>maxMessagesPerTask</code> option to control dynamic scaling up/down of threads.		Integer
camel.component.amqp.reply-to-on-timeout-max-concurrent-consumers	Specifies the maximum number of concurrent consumers for continue routing when timeout occurred when using request/reply over JMS.	1	Integer
camel.component.amqp.reply-to-override	Provides an explicit <code>ReplyTo</code> destination in the JMS message, which overrides the setting of <code>replyTo</code> . It is useful if you want to forward the message to a remote Queue and receive the reply message from the <code>ReplyTo</code> destination.		String
camel.component.amqp.reply-to-same-destination-allowed	Whether a JMS consumer is allowed to send a reply message to the same destination that the consumer is using to consume from. This prevents an endless loop by consuming and sending back the same message to itself.	false	Boolean
camel.component.amqp.reply-to-type	Allows for explicitly specifying which kind of strategy to use for <code>replyTo</code> queues when doing request/reply over JMS. Possible values are: <code>Temporary</code> , <code>Shared</code> , or <code>Exclusive</code> . By default Camel will use temporary queues. However if <code>replyTo</code> has been configured, then <code>Shared</code> is used by default. This option allows you to use exclusive queues instead of shared ones. See Camel JMS documentation for more details, and especially the notes about the implications if running in a clustered environment, and the fact that <code>Shared</code> reply queues has lower performance than its alternatives <code>Temporary</code> and <code>Exclusive</code> .		<code>ReplyToType</code>
camel.component.amqp.request-timeout	The timeout for waiting for a reply when using the InOut Exchange Pattern (in milliseconds). The default is 20 seconds. You can include the header <code>CamelJmsRequestTimeout</code> to override this endpoint configured timeout value, and thus have per message individual timeout values. See also the <code>requestTimeoutCheckerInterval</code> option. The option is a long type.	20000	Long

Name	Description	Default	Type
camel.component.amqp.request-timeout-checker-interval	Configures how often Camel should check for timed out Exchanges when doing request/reply over JMS. By default Camel checks once per second. But if you must react faster when a timeout occurs, then you can lower this interval, to check more frequently. The timeout is determined by the option requestTimeout. The option is a long type.	1000	Long
camel.component.amqp.selector	Sets the JMS selector to use.		String
camel.component.amqp.stream-message-type-enabled	Sets whether StreamMessage type is enabled or not. Message payloads of streaming kind such as files, InputStream, etc will either be sent as BytesMessage or StreamMessage. This option controls which kind will be used. By default BytesMessage is used which enforces the entire message payload to be read into memory. By enabling this option the message payload is read into memory in chunks and each chunk is then written to the StreamMessage until no more data.	false	Boolean
camel.component.amqp.subscription-durable	Set whether to make the subscription durable. The durable subscription name to be used can be specified through the subscriptionName property. Default is false. Set this to true to register a durable subscription, typically in combination with a subscriptionName value (unless your message listener class name is good enough as subscription name). Only makes sense when listening to a topic (pub-sub domain), therefore this method switches the pubSubDomain flag as well.	false	Boolean
camel.component.amqp.subscription-name	Set the name of a subscription to create. To be applied in case of a topic (pub-sub domain) with a shared or durable subscription. The subscription name needs to be unique within this client's JMS client id. Default is the class name of the specified message listener. Note: Only 1 concurrent consumer (which is the default of this message listener container) is allowed for each subscription, except for a shared subscription (which requires JMS 2.0).		String

Name	Description	Default	Type
camel.component.amqp.subscription-shared	Set whether to make the subscription shared. The shared subscription name to be used can be specified through the <code>subscriptionName</code> property. Default is false. Set this to true to register a shared subscription, typically in combination with a <code>subscriptionName</code> value (unless your message listener class name is good enough as subscription name). Note that shared subscriptions may also be durable, so this flag can (and often will) be combined with <code>subscriptionDurable</code> as well. Only makes sense when listening to a topic (pub-sub domain), therefore this method switches the <code>pubSubDomain</code> flag as well. Requires a JMS 2.0 compatible message broker.	false	Boolean
camel.component.amqp.synchronous	Sets whether synchronous processing should be strictly used.	false	Boolean
camel.component.amqp.task-executor	Allows you to specify a custom task executor for consuming messages. The option is a <code>org.springframework.core.task.TaskExecutor</code> type.		TaskExecutor
camel.component.amqp.test-connection-on-startup	Specifies whether to test the connection on startup. This ensures that when Camel starts that all the JMS consumers have a valid connection to the JMS broker. If a connection cannot be granted then Camel throws an exception on startup. This ensures that Camel is not started with failed connections. The JMS producers is tested as well.	false	Boolean
camel.component.amqp.time-to-live	When sending messages, specifies the time-to-live of the message (in milliseconds).	-1	Long
camel.component.amqp.transacted	Specifies whether to use transacted mode.	false	Boolean

Name	Description	Default	Type
camel.component.amqp.transacted-in-out	Specifies whether InOut operations (request reply) default to using transacted mode. If this flag is set to true, then Spring JmsTemplate will have sessionTransacted set to true, and the acknowledgeMode as transacted on the JmsTemplate used for InOut operations. Note from Spring JMS: that within a JTA transaction, the parameters passed to createQueue, createTopic methods are not taken into account. Depending on the Java EE transaction context, the container makes its own decisions on these values. Analogously, these parameters are not taken into account within a locally managed transaction either, since Spring JMS operates on an existing JMS Session in this case. Setting this flag to true will use a short local JMS transaction when running outside of a managed transaction, and a synchronized local JMS transaction in case of a managed transaction (other than an XA transaction) being present. This has the effect of a local JMS transaction being managed alongside the main transaction (which might be a native JDBC transaction), with the JMS transaction committing right after the main transaction.	false	Boolean
camel.component.amqp.transaction-manager	The Spring transaction manager to use. The option is a <code>org.springframework.transaction.PlatformTransactionManager</code> type.		PlatformTransactionManager
camel.component.amqp.transaction-name	The name of the transaction to use.		String
camel.component.amqp.transaction-timeout	The timeout value of the transaction (in seconds), if using transacted mode.	-1	Integer

Name	Description	Default	Type
camel.component.amqp.transfer-exception	If enabled and you are using Request Reply messaging (InOut) and an Exchange failed on the consumer side, then the caused Exception will be send back in response as a javax.jms.ObjectMessage. If the client is Camel, the returned Exception is rethrown. This allows you to use Camel JMS as a bridge in your routing - for example, using persistent queues to enable robust routing. Notice that if you also have transferExchange enabled, this option takes precedence. The caught exception is required to be serializable. The original Exception on the consumer side can be wrapped in an outer exception such as org.apache.camel.RuntimeCamelException when returned to the producer. Use this with caution as the data is using Java Object serialization and requires the received to be able to deserialize the data at Class level, which forces a strong coupling between the producers and consumer!.	false	Boolean
camel.component.amqp.transfer-exchange	You can transfer the exchange over the wire instead of just the body and headers. The following fields are transferred: In body, Out body, Fault body, In headers, Out headers, Fault headers, exchange properties, exchange exception. This requires that the objects are serializable. Camel will exclude any non-serializable objects and log it at WARN level. You must enable this option on both the producer and consumer side, so Camel knows the payloads is an Exchange and not a regular payload. Use this with caution as the data is using Java Object serialization and requires the receiver to be able to deserialize the data at Class level, which forces a strong coupling between the producers and consumers having to use compatible Camel versions!.	false	Boolean
camel.component.amqp.use-message-id-as-correlation-id	Specifies whether JMSMessageID should always be used as JMSCorrelationID for InOut messages.	false	Boolean
camel.component.amqp.username	Username to use with the ConnectionFactory. You can also configure username/password directly on the ConnectionFactory.		String
camel.component.amqp.wait-for-provision-correlation-to-be-updated-counter	Number of times to wait for provisional correlation id to be updated to the actual correlation id when doing request/reply over JMS and when the option useMessageIDAsCorrelationID is enabled.	50	Integer

Name	Description	Default	Type
<code>camel.component.amqp.wait-for-provision-correlation-to-be-updated-thread-sleeping-time</code>	Interval in millis to sleep each time while waiting for provisional correlation id to be updated. The option is a long type.	100	Long

CHAPTER 3. AVRO

This component provides a dataformat for avro, which allows serialization and deserialization of messages using Apache Avro's binary dataformat. Since Camel 3.2 rpc functionality was moved into separate **camel-avro-rpc** component.

You can easily generate classes from a schema, using maven, ant etc. More details can be found at the [Apache Avro documentation](#).

3.1. DEPENDENCIES

When using **camel-avro** with Red Hat build of Camel Spring Boot, add the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-avro-starter</artifactId>
</dependency>
```

3.2. AVRO DATAFORMAT OPTIONS

The Avro dataformat supports 1 options, which are listed below.

Name	Default	Java Type	Description
instanceClassName		String	Class name to use for marshal and unmarshalling.

3.3. AVRO DATA FORMAT USAGE

Using the avro data format is as easy as specifying that the class that you want to marshal or unmarshal in your route.

```
AvroDataFormat format = new AvroDataFormat(Value.SCHEMA$);

from("direct:in").marshal(format).to("direct:marshal");
from("direct:back").unmarshal(format).to("direct:unmarshal");
```

Where Value is an Avro Maven Plugin Generated class.

or in XML

```
<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="direct:in"/>
    <marshal>
      <avro instanceClass="org.apache.camel.dataformat.avro.Message"/>
    </marshal>
```

```

        <to uri="log:out"/>
    </route>
</camelContext>

```

An alternative can be to specify the dataformat inside the context and reference it from your route.

```

<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
    <dataFormats>
        <avro id="avro" instanceClass="org.apache.camel.dataformat.avro.Message"/>
    </dataFormats>
    <route>
        <from uri="direct:in"/>
        <marshal><custom ref="avro"/></marshal>
        <to uri="log:out"/>
    </route>
</camelContext>

```

In the same manner you can umarshal using the avro data format.

3.4. SPRING BOOT AUTO-CONFIGURATION

When using avro with Spring Boot make sure to add the Maven dependency to have support for auto configuration. The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.dataformat.avro.enabled	Whether to enable auto configuration of the avro data format. This is enabled by default.		Boolean
camel.dataformat.avro.instance-class-name	Class name to use for marshal and unmarshalling.		String

CHAPTER 4. AVRO JACKSON

Jackson Avro is a Data Format which uses the [Jackson library](#) with the [Avro extension](#) to unmarshal an Avro payload into Java objects or to marshal Java objects into an Avro payload.

NOTE

If you are familiar with Jackson, this Avro data format behaves in the same way as its JSON counterpart, and thus can be used with classes annotated for JSON serialization/deserialization.

```
from("kafka:topic").
  unmarshal().avro(AvroLibrary.Jackson, JsonNode.class).
  to("log:info");
```

4.1. DEPENDENCIES

When using **avro-jackson** with Red Hat build of Camel Spring Boot make sure to add the Maven dependency to have support for auto configuration.

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-jackson-avro-starter</artifactId>
</dependency>
```

4.2. CONFIGURING THE SCHEMARESOLVER

Since Avro serialization is schema-based, this data format requires that you provide a SchemaResolver object that is able to lookup the schema for each exchange that is going to be marshalled/unmarshalled.

You can add a single SchemaResolver to the registry and it will be looked up automatically. Or you can explicitly specify the reference to a custom SchemaResolver.

4.3. AVRO JACKSON OPTIONS

The Avro Jackson dataformat supports 18 options, which are listed below.

Name	Default	Java Type	Description
objectMapper		String	Lookup and use the existing ObjectMapper with the given id when using Jackson.
useDefaultObjectMapper		Boolean	Whether to lookup and use default Jackson ObjectMapper from the registry.
unmarshalType		String	Class name of the java type to use when unmarshalling.

Name	Default	Java Type	Description
jsonView		String	When marshalling a POJO to JSON you might want to exclude certain fields from the JSON output. With Jackson you can use JSON views to accomplish this. This option is to refer to the class which has JsonView annotations.
include		String	If you want to marshal a pojo to JSON, and the pojo has some fields with null values. And you want to skip these null values, you can set this option to NON_NULL.
allowJmsType		Boolean	Used for JMS users to allow the JMSType header from the JMS spec to specify a FQN classname to use to unmarshal to.
collectionType		String	Refers to a custom collection type to lookup in the registry to use. This option should rarely be used, but allows to use different collection types than java.util.Collection based as default.
useList		Boolean	To unmarshal to a List of Map or a List of Pojo.
moduleClassNames		String	To use custom Jackson modules com.fasterxml.jackson.databind.Module specified as a String with FQN class names. Multiple classes can be separated by comma.
moduleRefs		String	To use custom Jackson modules referred from the Camel registry. Multiple modules can be separated by comma.
enableFeatures		String	Set of features to enable on the Jackson com.fasterxml.jackson.databind.ObjectMapper. The features should be a name that matches a enum from com.fasterxml.jackson.databind.SerializationFeature, com.fasterxml.jackson.databind.DeserializationFeature, or com.fasterxml.jackson.databind.MapperFeature Multiple features can be separated by comma.
disableFeatures		String	Set of features to disable on the Jackson com.fasterxml.jackson.databind.ObjectMapper. The features should be a name that matches a enum from com.fasterxml.jackson.databind.SerializationFeature, com.fasterxml.jackson.databind.DeserializationFeature, or com.fasterxml.jackson.databind.MapperFeature Multiple features can be separated by comma.

Name	Default	Java Type	Description
allowUnmarshalType		Boolean	If enabled then Jackson is allowed to attempt to use the CamelJacksonUnmarshalType header during the unmarshalling. This should only be enabled when desired to be used.
timezone		String	If set then Jackson will use the Timezone when marshalling/unmarshalling.
autoDiscoverObjectMapper		Boolean	If set to true then Jackson will lookup for an objectMapper into the registry.
contentTypeHeader		Boolean	Whether the data format should set the Content-Type header with the type from the data format. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON.
schemaResolver		String	Optional schema resolver used to lookup schemas for the data in transit.
autoDiscoverSchemaResolver		Boolean	When not disabled, the SchemaResolver will be looked up into the registry.

4.4. USING CUSTOM AVROMAPPER

You can configure **JacksonAvroDataFormat** to use a custom **AvroMapper** in case you need more control of the mapping configuration.

If you setup a single **AvroMapper** in the registry, then Camel will automatic lookup and use this **AvroMapper**.

4.5. SPRING BOOT AUTO-CONFIGURATION

The component supports 19 options, which are listed below.

Name	Description	Default	Type
camel.dataformat.avro-jackson.allow-jms-type	Used for JMS users to allow the JMSType header from the JMS spec to specify a FQN classname to use to unmarshal to.	false	Boolean

Name	Description	Default	Type
<code>camel.dataformat.avro-jackson.allow-unmarshall-type</code>	If enabled then Jackson is allowed to attempt to use the <code>CamelJacksonUnmarshalType</code> header during the unmarshalling. This should only be enabled when desired to be used.	false	Boolean
<code>camel.dataformat.avro-jackson.auto-discover-object-mapper</code>	If set to true then Jackson will lookup for an <code>objectMapper</code> into the registry.	false	Boolean
<code>camel.dataformat.avro-jackson.auto-discover-schema-resolver</code>	When not disabled, the <code>SchemaResolver</code> will be looked up into the registry.	true	Boolean
<code>camel.dataformat.avro-jackson.collection-type</code>	Refers to a custom collection type to lookup in the registry to use. This option should rarely be used, but allows to use different collection types than <code>java.util.Collection</code> based as default.		String
<code>camel.dataformat.avro-jackson.content-type-header</code>	Whether the data format should set the <code>Content-Type</code> header with the type from the data format. For example <code>application/xml</code> for data formats marshalling to XML, or <code>application/json</code> for data formats marshalling to JSON.	true	Boolean
<code>camel.dataformat.avro-jackson.disable-features</code>	Set of features to disable on the Jackson <code>com.fasterxml.jackson.databind.ObjectMapper</code> . The features should be a name that matches a enum from <code>com.fasterxml.jackson.databind.SerializationFeature</code> , <code>com.fasterxml.jackson.databind.DeserializationFeature</code> , or <code>com.fasterxml.jackson.databind.MapperFeature</code> . Multiple features can be separated by comma.		String
<code>camel.dataformat.avro-jackson.enable-features</code>	Set of features to enable on the Jackson <code>com.fasterxml.jackson.databind.ObjectMapper</code> . The features should be a name that matches a enum from <code>com.fasterxml.jackson.databind.SerializationFeature</code> , <code>com.fasterxml.jackson.databind.DeserializationFeature</code> , or <code>com.fasterxml.jackson.databind.MapperFeature</code> . Multiple features can be separated by comma.		String
<code>camel.dataformat.avro-jackson.enabled</code>	Whether to enable auto configuration of the avro-jackson data format. This is enabled by default.		Boolean

Name	Description	Default	Type
<code>camel.dataformat.avro-jackson.include</code>	If you want to marshal a pojo to JSON, and the pojo has some fields with null values. And you want to skip these null values, you can set this option to <code>NON_NULL</code> .		String
<code>camel.dataformat.avro-jackson.json-view</code>	When marshalling a POJO to JSON you might want to exclude certain fields from the JSON output. With Jackson you can use JSON views to accomplish this. This option is to refer to the class which has <code>JsonView</code> annotations.		String
<code>camel.dataformat.avro-jackson.module-class-names</code>	To use custom Jackson modules <code>com.fasterxml.jackson.databind.Module</code> specified as a String with FQN class names. Multiple classes can be separated by comma.		String
<code>camel.dataformat.avro-jackson.module-refs</code>	To use custom Jackson modules referred from the Camel registry. Multiple modules can be separated by comma.		String
<code>camel.dataformat.avro-jackson.object-mapper</code>	Lookup and use the existing ObjectMapper with the given id when using Jackson.		String
<code>camel.dataformat.avro-jackson.schema-resolver</code>	Optional schema resolver used to lookup schemas for the data in transit.		String
<code>camel.dataformat.avro-jackson.timezone</code>	If set then Jackson will use the Timezone when marshalling/unmarshalling.		String
<code>camel.dataformat.avro-jackson.unmarshal-type</code>	Class name of the java type to use when unmarshalling.		String
<code>camel.dataformat.avro-jackson.use-default-object-mapper</code>	Whether to lookup and use default Jackson ObjectMapper from the registry.	true	Boolean

Name	Description	Default	Type
<code>camel.dataformat.avro-jackson.use-list</code>	To unmarshal to a List of Map or a List of Pojo.	false	Boolean

CHAPTER 5. AWS CLOUDWATCH

Only producer is supported

The AWS2 Cloudwatch component allows messages to be sent to an [Amazon CloudWatch](#) metrics. The implementation of the Amazon API is provided by the [AWS SDK](#).

Prerequisites

You must have a valid Amazon Web Services developer account, and be signed up to use Amazon CloudWatch. More information is available at [Amazon CloudWatch](#).

5.1. DEPENDENCIES

When using **aws2-cw** with Red Hat build of Camel Spring Boot, add the following Maven dependency to your **pom.xml** to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-aws2-cw-starter</artifactId>
</dependency>
```

5.2. URI FORMAT

```
aws2-cw://namespace[?options]
```

The metrics will be created if they don't already exists. You can append query options to the URI in the following format, **?options=value&option2=value&...**

5.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

5.3.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).
- directly in the Java code.

5.3.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

5.4. COMPONENT OPTIONS

The AWS CloudWatch component supports 18 options, which are listed below.

Name	Description	Default	Type
amazonCwClient (producer)	Autowired To use the AmazonCloudWatch as the client.		CloudWatchClient
configuration (producer)	The component configuration.		Cw2Configuration
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
name (producer)	The metric name.		String

Name	Description	Default	Type
overrideEndpoint (producer)	Set the need for overriding the endpoint. This option needs to be used in combination with uriEndpointOverride option.	false	boolean
proxyHost (producer)	To define a proxy host when instantiating the CW client.		String
proxyPort (producer)	To define a proxy port when instantiating the CW client.		Integer
proxyProtocol (producer)	To define a proxy protocol when instantiating the CW client. Enum values: • HTTP • HTTPS	HTTPS	Protocol
region (producer)	The region in which CW client needs to work. When using this parameter, the configuration will expect the lowercase name of the region (for example ap-east-1) You'll need to use the name Region.EU_WEST_1.id().		String
timestamp (producer)	The metric timestamp.		Instant
trustAllCertificates (producer)	If we want to trust all certificates in case of overriding the endpoint.	false	boolean
unit (producer)	The metric unit.		String
uriEndpointOverride (producer)	Set the overriding uri endpoint. This option needs to be used in combination with overrideEndpoint option.		String
useDefaultCredentialsProvider (producer)	Set whether the S3 client should expect to load credentials through a default credentials provider or to expect static credentials to be passed in.	false	boolean
value (producer)	The metric value.		Double

Name	Description	Default	Type
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
accessKey (security)	Amazon AWS Access Key.		String
secretKey (security)	Amazon AWS Secret Key.		String

5.5. ENDPOINT OPTIONS

The AWS CloudWatch endpoint is configured using URI syntax:

```
aws2-cw:namespace
```

with the following path and query parameters:

5.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
namespace (producer)	Required The metric namespace.		String

5.5.2. Query Parameters (16 parameters)

Name	Description	Default	Type
amazonCwClient (producer)	Autowired To use the AmazonCloudWatch as the client.		CloudWatchClient

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
name (producer)	The metric name.		String
overrideEndpoint (producer)	Set the need for overriding the endpoint. This option needs to be used in combination with uriEndpointOverride option.	false	boolean
proxyHost (producer)	To define a proxy host when instantiating the CW client.		String
proxyPort (producer)	To define a proxy port when instantiating the CW client.		Integer
proxyProtocol (producer)	To define a proxy protocol when instantiating the CW client. Enum values: • HTTP • HTTPS	HTTPS	Protocol
region (producer)	The region in which CW client needs to work. When using this parameter, the configuration will expect the lowercase name of the region (for example ap-east-1) You'll need to use the name Region.EU_WEST_1.id().		String
timestamp (producer)	The metric timestamp.		Instant
trustAllCertificates (producer)	If we want to trust all certificates in case of overriding the endpoint.	false	boolean
unit (producer)	The metric unit.		String

Name	Description	Default	Type
uriEndpointOverride (producer)	Set the overriding uri endpoint. This option needs to be used in combination with <code>overrideEndpoint</code> option.		String
useDefaultCredentialsProvider (producer)	Set whether the S3 client should expect to load credentials through a default credentials provider or to expect static credentials to be passed in.	false	boolean
value (producer)	The metric value.		Double
accessKey (security)	Amazon AWS Access Key.		String
secretKey (security)	Amazon AWS Secret Key.		String

Required CW component options

You have to provide the `amazonCwClient` in the Registry or your `accessKey` and `secretKey` to access the [Amazon's CloudWatch](#).

5.6. USAGE

5.6.1. Static credentials vs Default Credential Provider

You have the possibility of avoiding the usage of explicit static credentials, by specifying the `useDefaultCredentialsProvider` option and set it to true.

- Java system properties - `aws.accessKeyId` and `aws.secretKey`
- Environment variables - `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`.
- Web Identity Token from AWS STS.
- The shared credentials and config files.
- Amazon ECS container credentials - loaded from the Amazon ECS if the environment variable `AWS_CONTAINER_CREDENTIALS_RELATIVE_URI` is set.
- Amazon EC2 Instance profile credentials.

For more information about this you can look at [AWS credentials documentation](#)

5.6.2. Message headers evaluated by the CW producer

Header	Type	Description
CamelAwsCwMetricName	String	The Amazon CW metric name.

Header	Type	Description
CamelAwsCwMetricValue	Double	The Amazon CW metric value.
CamelAwsCwMetricUnit	String	The Amazon CW metric unit.
CamelAwsCwMetricName space	String	The Amazon CW metric namespace.
CamelAwsCwMetricTimes tamp	Date	The Amazon CW metric timestamp.
CamelAwsCwMetricDime nsionName	String	The Amazon CW metric dimension name.
CamelAwsCwMetricDime nsionValue	String	The Amazon CW metric dimension value.
CamelAwsCwMetricDime nsions	Map<String, String>	A map of dimension names and dimension values.

5.6.3. Advanced CloudWatchClient configuration

If you need more control over the **CloudWatchClient** instance configuration you can create your own instance and refer to it from the URI:

```
from("direct:start")
.to("aws2-cw://namespace?amazonCwClient=#client");
```

The **#client** refers to a **CloudWatchClient** in the Registry.

5.7. EXAMPLES

5.7.1. Producer Example

```
from("direct:start")
.to("aws2-cw://http://camel.apache.org/aws-cw");
```

and sends something like

```
exchange.getIn().setHeader(Cw2Constants.METRIC_NAME, "ExchangesCompleted");
exchange.getIn().setHeader(Cw2Constants.METRIC_VALUE, "2.0");
exchange.getIn().setHeader(Cw2Constants.METRIC_UNIT, "Count");
```

5.8. SPRING BOOT AUTO-CONFIGURATION

The component supports 19 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.aws2-cw.access-key</code>	Amazon AWS Access Key.		String
<code>camel.component.aws2-cw.amazon-cw-client</code>	To use the AmazonCloudWatch as the client. The option is a <code>software.amazon.awssdk.services.cloudwatch.CloudWatchClient</code> type.		CloudWatchClient
<code>camel.component.aws2-cw.autowired-enabled</code>	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
<code>camel.component.aws2-cw.configuration</code>	The component configuration. The option is a <code>org.apache.camel.component.aws2.cw.Cw2Configuration</code> type.		Cw2Configuration
<code>camel.component.aws2-cw.enabled</code>	Whether to enable auto configuration of the <code>aws2-cw</code> component. This is enabled by default.		Boolean
<code>camel.component.aws2-cw.lazy-start-producer</code>	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
<code>camel.component.aws2-cw.name</code>	The metric name.		String
<code>camel.component.aws2-cw.override-endpoint</code>	Set the need for overriding the endpoint. This option needs to be used in combination with <code>uriEndpointOverride</code> option.	false	Boolean
<code>camel.component.aws2-cw.proxy-host</code>	To define a proxy host when instantiating the CW client.		String

Name	Description	Default	Type
<code>camel.component.aws2-cw.proxy-port</code>	To define a proxy port when instantiating the CW client.		Integer
<code>camel.component.aws2-cw.proxy-protocol</code>	To define a proxy protocol when instantiating the CW client.		Protocol
<code>camel.component.aws2-cw.region</code>	The region in which CW client needs to work. When using this parameter, the configuration will expect the lowercase name of the region (for example ap-east-1) You'll need to use the name <code>Region.EU_WEST_1.id()</code> .		String
<code>camel.component.aws2-cw.secret-key</code>	Amazon AWS Secret Key.		String
<code>camel.component.aws2-cw.timestamp</code>	The metric timestamp. The option is a <code>java.time.Instant</code> type.		Instant
<code>camel.component.aws2-cw.trust-all-certificates</code>	If we want to trust all certificates in case of overriding the endpoint.	false	Boolean
<code>camel.component.aws2-cw.unit</code>	The metric unit.		String
<code>camel.component.aws2-cw.uri-endpoint-override</code>	Set the overriding uri endpoint. This option needs to be used in combination with <code>overrideEndpoint</code> option.		String
<code>camel.component.aws2-cw.use-default-credentials-provider</code>	Set whether the S3 client should expect to load credentials through a default credentials provider or to expect static credentials to be passed in.	false	Boolean
<code>camel.component.aws2-cw.value</code>	The metric value.		Double

CHAPTER 6. AWS DYNAMODB

Only producer is supported

The AWS2 DynamoDB component supports storing and retrieving data from/to service.

Prerequisites

You must have a valid Amazon Web Services developer account, and be signed up to use Amazon DynamoDB. More information is available at [Amazon DynamoDB](#).

6.1. DEPENDENCIES

When using **aws2-ddb** Red Hat build of Camel Spring Boot, add the following Maven dependency to your **pom.xml** to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-aws2-ddb-starter</artifactId>
</dependency>
```

6.2. URI FORMAT

```
aws2-ddb://domainName[?options]
```

You can append query options to the URI in the following format, **?options=value&option2=value&...**

6.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

6.3.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).
- directly in the Java code.

6.3.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

6.4. COMPONENT OPTIONS

The AWS DynamoDB component supports 22 options, which are listed below.

Name	Description	Default	Type
amazonDDBClient (producer)	Autowired To use the AmazonDynamoDB as the client.		DynamoDbClient
configuration (producer)	The component configuration.		Ddb2Configuration
consistentRead (producer)	Determines whether or not strong consistency should be enforced when data is read.	false	boolean
enabledInitialDescribeTable (producer)	Set whether the initial Describe table operation in the DDB Endpoint must be done, or not.	true	boolean
keyAttributeName (producer)	Attribute name when creating table.		String
keyAttributeType (producer)	Attribute type when creating table.		String
keyScalarType (producer)	The key scalar type, it can be S (String), N (Number) and B (Bytes).		String

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
operation (producer)	What operation to perform. Enum values: ● BatchGetItems ● DeleteItem ● DeleteTable ● DescribeTable ● GetItem ● PutItem ● Query ● Scan ● UpdateItem ● UpdateTable	PutItem	Ddb2Operations
overrideEndpoint (producer)	Set the need for overriding the endpoint. This option needs to be used in combination with uriEndpointOverride option.	false	boolean
proxyHost (producer)	To define a proxy host when instantiating the DDB client.		String
proxyPort (producer)	The region in which DynamoDB client needs to work. When using this parameter, the configuration will expect the lowercase name of the region (for example ap-east-1) You'll need to use the name Region.EU_WEST_1.id().		Integer

Name	Description	Default	Type
proxyProtocol (producer)	To define a proxy protocol when instantiating the DDB client. Enum values: • HTTP • HTTPS	HTTPS	Protocol
readCapacity (producer)	The provisioned throughput to reserve for reading resources from your table.		Long
region (producer)	The region in which DDB client needs to work.		String
trustAllCertificates (producer)	If we want to trust all certificates in case of overriding the endpoint.	false	boolean
uriEndpointOverride (producer)	Set the overriding uri endpoint. This option needs to be used in combination with <code>overrideEndpoint</code> option.		String
useDefaultCredentialsProvider (producer)	Set whether the S3 client should expect to load credentials through a default credentials provider or to expect static credentials to be passed in.	false	boolean
writeCapacity (producer)	The provisioned throughput to reserved for writing resources to your table.		Long
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
accessKey (security)	Amazon AWS Access Key.		String
secretKey (security)	Amazon AWS Secret Key.		String

6.5. ENDPOINT OPTIONS

The AWS DynamoDB endpoint is configured using URI syntax:

```
aws2-ddb:tableName
```

with the following path and query parameters:

6.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
tableName (producer)	Required The name of the table currently worked with.		String

6.5.2. Query Parameters (20 parameters)

Name	Description	Default	Type
amazonDDBClient (producer)	Autowired To use the AmazonDynamoDB as the client.		DynamoDbClient
consistentRead (producer)	Determines whether or not strong consistency should be enforced when data is read.	false	boolean
enabledInitialDescribeTable (producer)	Set whether the initial Describe table operation in the DDB Endpoint must be done, or not.	true	boolean
keyAttributeName (producer)	Attribute name when creating table.		String
keyAttributeType (producer)	Attribute type when creating table.		String
keyScalarType (producer)	The key scalar type, it can be S (String), N (Number) and B (Bytes).		String
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

Name	Description	Default	Type
operation (producer)	What operation to perform. Enum values: • BatchGetItems • DeleteItem • DeleteTable • DescribeTable • GetItem • PutItem • Query • Scan • UpdateItem • UpdateTable	PutItem	Ddb2Operations
overrideEndpoint (producer)	Set the need for overriding the endpoint. This option needs to be used in combination with uriEndpointOverride option.	false	boolean
proxyHost (producer)	To define a proxy host when instantiating the DDB client.		String
proxyPort (producer)	The region in which DynamoDB client needs to work. When using this parameter, the configuration will expect the lowercase name of the region (for example ap-east-1) You'll need to use the name Region.EU_WEST_1.id().		Integer
proxyProtocol (producer)	To define a proxy protocol when instantiating the DDB client. Enum values: • HTTP • HTTPS	HTTPS	Protocol
readCapacity (producer)	The provisioned throughput to reserve for reading resources from your table.		Long
region (producer)	The region in which DDB client needs to work.		String

Name	Description	Default	Type
trustAllCertificates (producer)	If we want to trust all certificates in case of overriding the endpoint.	false	boolean
uriEndpointOverride (producer)	Set the overriding uri endpoint. This option needs to be used in combination with <code>overrideEndpoint</code> option.		String
useDefaultCredentialsProvider (producer)	Set whether the S3 client should expect to load credentials through a default credentials provider or to expect static credentials to be passed in.	false	boolean
writeCapacity (producer)	The provisioned throughput to reserved for writing resources to your table.		Long
accessKey (security)	Amazon AWS Access Key.		String
secretKey (security)	Amazon AWS Secret Key.		String

Required DDB component options

You have to provide the `amazonDDBClient` in the Registry or your `accessKey` and `secretKey` to access the [Amazon's DynamoDB](#).

6.6. USAGE

6.6.1. Static credentials vs Default Credential Provider

You have the possibility of avoiding the usage of explicit static credentials, by specifying the `useDefaultCredentialsProvider` option and set it to true.

- Java system properties - `aws.accessKeyId` and `aws.secretKey`
- Environment variables - `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`.
- Web Identity Token from AWS STS.
- The shared credentials and config files.
- Amazon ECS container credentials - loaded from the Amazon ECS if the environment variable `AWS_CONTAINER_CREDENTIALS_RELATIVE_URI` is set.
- Amazon EC2 Instance profile credentials.

For more information about this you can look at [AWS credentials documentation](#)

6.6.2. Message headers evaluated by the DDB producer

Header	Type	Description
CamelAwsDdbBatchItems	Map<String, KeysAndAttributes>	A map of the table name and corresponding items to get by primary key.
CamelAwsDdbTableName	String	Table Name for this operation.
CamelAwsDdbKey	Key	The primary key that uniquely identifies each item in a table.
CamelAwsDdbReturnValues	String	Use this parameter if you want to get the attribute name-value pairs before or after they are modified(NONE, ALL_OLD, UPDATED_OLD, ALL_NEW, UPDATED_NEW).
CamelAwsDdbUpdateCondition	Map<String, ExpectedAttributeValue>	Designates an attribute for a conditional modification.
CamelAwsDdbAttributeNames	Collection<String>	If attribute names are not specified then all attributes will be returned.
CamelAwsDdbConsistentRead	Boolean	If set to true, then a consistent read is issued, otherwise eventually consistent is used.
CamelAwsDdbIndexName	String	If set will be used as Secondary Index for Query operation.
CamelAwsDdbItem	Map<String, AttributeValue>	A map of the attributes for the item, and must include the primary key values that define the item.
CamelAwsDdbExactCount	Boolean	If set to true, Amazon DynamoDB returns a total number of items that match the query parameters, instead of a list of the matching items and their attributes.
CamelAwsDdbKeyConditions	Map<String, Condition>	This header specify the selection criteria for the query, and merge together the two old headers CamelAwsDdbHashKeyValue and CamelAwsDdbScanRangeKeyCondition
CamelAwsDdbStartKey	Key	Primary key of the item from which to continue an earlier query.
CamelAwsDdbHashKeyValue	AttributeValue	Value of the hash component of the composite primary key.
CamelAwsDdbLimit	Integer	The maximum number of items to return.

Header	Type	Description
CamelAwsDdbScanRangeKeyCondition	Condition	A container for the attribute values and comparison operators to use for the query.
CamelAwsDdbScanIndexForward	Boolean	Specifies forward or backward traversal of the index.
CamelAwsDdbScanFilter	Map<String, Condition>	Evaluates the scan results and returns only the desired values.
CamelAwsDdbUpdateValues	Map<String, AttributeValueUpdate>	Map of attribute name to the new value and action for the update.

6.6.3. Message headers set during BatchGetItems operation

Header	Type	Description
CamelAwsDdbBatchResponse	Map<String, BatchResponse>	Table names and the respective item attributes from the tables.
CamelAwsDdbUnprocessedKeys	Map<String, KeysAndAttributes>	Contains a map of tables and their respective keys that were not processed with the current response.

6.6.4. Message headers set during DeleteItem operation

Header	Type	Description
CamelAwsDdbAttributes	Map<String, AttributeValue>	The list of attributes returned by the operation.

6.6.5. Message headers set during DeleteTable operation

Header	Type	Description
CamelAwsDdbProvisionedThroughput		
ProvisionedThroughputDescription		The value of the ProvisionedThroughput property for this table

Header	Type	Description
CamelAwsDdbCreationDate	Date	Creation DateTime of this table.
CamelAwsDdbTableItemCount	Long	Item count for this table.
CamelAwsDdbKeySchema	KeySchema	The KeySchema that identifies the primary key for this table. From Camel 2.16.0 the type of this header is List<KeySchemaElement> and not KeySchema
CamelAwsDdbTableName	String	The table name.
CamelAwsDdbTableSize	Long	The table size in bytes.
CamelAwsDdbTableStatus	String	The status of the table: CREATING, UPDATING, DELETING, ACTIVE

6.6.6. Message headers set during DescribeTable operation

Header	Type	Description
CamelAwsDdbProvisionedThroughput	<code>\ {{ProvisionedThroughputDescription}} }</code>	The value of the ProvisionedThroughput property for this table
CamelAwsDdbCreationDate	Date	Creation DateTime of this table.
CamelAwsDdbTableItemCount	Long	Item count for this table.
CamelAwsDdbKeySchema	<code>{{KeySchema}}</code>	The KeySchema that identifies the primary key for this table.
CamelAwsDdbTableName	String	The table name.
CamelAwsDdbTableSize	Long	The table size in bytes.
CamelAwsDdbTableStatus	String	The status of the table: CREATING, UPDATING, DELETING, ACTIVE
CamelAwsDdbReadCapacity	Long	ReadCapacityUnits property of this table.
CamelAwsDdbWriteCapacity	Long	WriteCapacityUnits property of this table.

6.6.7. Message headers set during GetItem operation

Header	Type	Description
CamelAwsDdbAttributes	Map<String, AttributeValue>	The list of attributes returned by the operation.

6.6.8. Message headers set during PutItem operation

Header	Type	Description
CamelAwsDdbAttributes	Map<String, AttributeValue>	The list of attributes returned by the operation.

6.6.9. Message headers set during Query operation

Header	Type	Description
CamelAwsDdbItems	List<java.util.Map<String, AttributeValue>>	The list of attributes returned by the operation.
CamelAwsDdbLastEvaluatedKey	Key	Primary key of the item where the query operation stopped, inclusive of the previous result set.
CamelAwsDdbConsumedCapacity	Double	The number of Capacity Units of the provisioned throughput of the table consumed during the operation.
CamelAwsDdbCount	Integer	Number of items in the response.

6.6.10. Message headers set during Scan operation

Header	Type	Description
CamelAwsDdbItems	List<java.util.Map<String, AttributeValue>>	The list of attributes returned by the operation.
CamelAwsDdbLastEvaluatedKey	Key	Primary key of the item where the query operation stopped, inclusive of the previous result set.
CamelAwsDdbConsumedCapacity	Double	The number of Capacity Units of the provisioned throughput of the table consumed during the operation.

Header	Type	Description
CamelAwsDdbCount	Integer	Number of items in the response.
CamelAwsDdbScannedCount	Integer	Number of items in the complete scan before any filters are applied.

6.6.11. Message headers set during UpdateItem operation

Header	Type	Description
CamelAwsDdbAttributes	Map<String, AttributeValue>	The list of attributes returned by the operation.

6.6.12. Advanced AmazonDynamoDB configuration

If you need more control over the **AmazonDynamoDB** instance configuration you can create your own instance and refer to it from the URI:

```
from("direct:start")
.to("aws2-ddb://domainName?amazonDDBClient=#client");
```

The **#client** refers to a **DynamoDbClient** in the Registry.

6.7. SUPPORTED PRODUCER OPERATIONS

- BatchGetItems
- DeleteItem
- DeleteTable
- DescribeTable
- GetItem
- PutItem
- Query
- Scan
- UpdateItem
- UpdateTable

6.8. EXAMPLES

6.8.1. Producer Examples

- PutItem: this operation will create an entry into DynamoDB

```
from("direct:start")
  .setHeader(Ddb2Constants.OPERATION, Ddb2Operations.PutItem)
  .setHeader(Ddb2Constants.CONSISTENT_READ, "true")
  .setHeader(Ddb2Constants.RETURN_VALUES, "ALL_OLD")
  .setHeader(Ddb2Constants.ITEM, attributeMap)
  .setHeader(Ddb2Constants.ATTRIBUTE_NAMES, attributeMap.keySet());
  .to("aws2-ddb://" + tableName + "?keyAttributeName=" + attributeName + "&keyAttributeType=" +
    KeyType.HASH
    + "&keyScalarType=" + ScalarAttributeType.S
    + "&readCapacity=1&writeCapacity=1");
```

Maven users will need to add the following dependency to their pom.xml.

pom.xml

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-aws2-ddb</artifactId>
  <version>${camel-version}</version>
</dependency>
```

where **{camel-version}** must be replaced by the actual version of Camel.

6.9. SPRING BOOT AUTO-CONFIGURATION

The component supports 40 options, which are listed below.

Name	Description	Default	Type
camel.component.aws2-ddb.access-key	Amazon AWS Access Key.		String
camel.component.aws2-ddb.amazon-d-d-b-client	To use the AmazonDynamoDB as the client. The option is a software.amazon.awssdk.services.dynamodb.DynamoDbClient type.		DynamoDbClient
camel.component.aws2-ddb.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.aws2-ddb.configuration	The component configuration. The option is a org.apache.camel.component.aws2.ddb.Ddb2Configuration type.		Ddb2Configuration

Name	Description	Default	Type
<code>camel.component.aws2-ddb.consistent-read</code>	Determines whether or not strong consistency should be enforced when data is read.	false	Boolean
<code>camel.component.aws2-ddb.enabled</code>	Whether to enable auto configuration of the aws2-ddb component. This is enabled by default.		Boolean
<code>camel.component.aws2-ddb.enabled-initial-describe-table</code>	Set whether the initial Describe table operation in the DDB Endpoint must be done, or not.	true	Boolean
<code>camel.component.aws2-ddb.key-attribute-name</code>	Attribute name when creating table.		String
<code>camel.component.aws2-ddb.key-attribute-type</code>	Attribute type when creating table.		String
<code>camel.component.aws2-ddb.key-scalar-type</code>	The key scalar type, it can be S (String), N (Number) and B (Bytes).		String
<code>camel.component.aws2-ddb.lazy-start-producer</code>	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
<code>camel.component.aws2-ddb.operation</code>	What operation to perform.		Ddb2Operations
<code>camel.component.aws2-ddb.override-endpoint</code>	Set the need for overriding the endpoint. This option needs to be used in combination with uriEndpointOverride option.	false	Boolean

Name	Description	Default	Type
<code>camel.component.aws2-ddb.proxy-host</code>	To define a proxy host when instantiating the DDB client.		String
<code>camel.component.aws2-ddb.proxy-port</code>	The region in which DynamoDB client needs to work. When using this parameter, the configuration will expect the lowercase name of the region (for example ap-east-1) You'll need to use the name <code>Region.EU_WEST_1.id()</code> .		Integer
<code>camel.component.aws2-ddb.proxy-protocol</code>	To define a proxy protocol when instantiating the DDB client.		Protocol
<code>camel.component.aws2-ddb.read-capacity</code>	The provisioned throughput to reserve for reading resources from your table.		Long
<code>camel.component.aws2-ddb.region</code>	The region in which DDB client needs to work.		String
<code>camel.component.aws2-ddb.secret-key</code>	Amazon AWS Secret Key.		String
<code>camel.component.aws2-ddb.trust-all-certificates</code>	If we want to trust all certificates in case of overriding the endpoint.	false	Boolean
<code>camel.component.aws2-ddb.uri-endpoint-override</code>	Set the overriding uri endpoint. This option needs to be used in combination with <code>overrideEndpoint</code> option.		String
<code>camel.component.aws2-ddb.use-default-credentials-provider</code>	Set whether the S3 client should expect to load credentials through a default credentials provider or to expect static credentials to be passed in.	false	Boolean
<code>camel.component.aws2-ddb.write-capacity</code>	The provisioned throughput to reserved for writing resources to your table.		Long

Name	Description	Default	Type
<code>camel.component.aws2-ddbstream.access-key</code>	Amazon AWS Access Key.		String
<code>camel.component.aws2-ddbstream.amazon-dynamo-db-streams-client</code>	Amazon DynamoDB client to use for all requests for this endpoint. The option is a <code>software.amazon.awssdk.services.dynamodb.streams.DynamoDbStreamsClient</code> type.		<code>DynamoDbStreamsClient</code>
<code>camel.component.aws2-ddbstream.autowired-enabled</code>	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
<code>camel.component.aws2-ddbstream.bridge-error-handler</code>	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
<code>camel.component.aws2-ddbstream.configuration</code>	The component configuration. The option is a <code>org.apache.camel.component.aws2.ddbstream.Ddb2StreamConfiguration</code> type.		<code>Ddb2StreamConfiguration</code>
<code>camel.component.aws2-ddbstream.enabled</code>	Whether to enable auto configuration of the <code>aws2-ddbstream</code> component. This is enabled by default.		Boolean
<code>camel.component.aws2-ddbstream.max-results-per-request</code>	Maximum number of records that will be fetched in each poll.		Integer
<code>camel.component.aws2-ddbstream.override-endpoint</code>	Set the need for overriding the endpoint. This option needs to be used in combination with <code>uriEndpointOverride</code> option.	false	Boolean

Name	Description	Default	Type
<code>camel.component.aws2-ddbstream.proxy-host</code>	To define a proxy host when instantiating the DDBStreams client.		String
<code>camel.component.aws2-ddbstream.proxy-port</code>	To define a proxy port when instantiating the DDBStreams client.		Integer
<code>camel.component.aws2-ddbstream.proxy-protocol</code>	To define a proxy protocol when instantiating the DDBStreams client.		Protocol
<code>camel.component.aws2-ddbstream.region</code>	The region in which DDBStreams client needs to work.		String
<code>camel.component.aws2-ddbstream.secret-key</code>	Amazon AWS Secret Key.		String
<code>camel.component.aws2-ddbstream.stream-iterator-type</code>	Defines where in the DynamoDB stream to start getting records. Note that using FROM_START can cause a significant delay before the stream has caught up to real-time.		Ddb2StreamConfiguration\$StreamIteratorType
<code>camel.component.aws2-ddbstream.trust-all-certificates</code>	If we want to trust all certificates in case of overriding the endpoint.	false	Boolean
<code>camel.component.aws2-ddbstream.uri-endpoint-override</code>	Set the overriding uri endpoint. This option needs to be used in combination with overrideEndpoint option.		String
<code>camel.component.aws2-ddbstream.use-default-credentials-provider</code>	Set whether the DynamoDB Streams client should expect to load credentials through a default credentials provider or to expect static credentials to be passed in.	false	Boolean

CHAPTER 7. AWS KINESIS

Both producer and consumer are supported

The AWS2 Kinesis component supports receiving messages from and sending messages to Amazon Kinesis (no Batch supported) service.

The AWS2 Kinesis component also supports Synchronous and Asynchronous Client. So if you need the connection (client) to be async, configure the 'asyncClient' option (can be found in DSL also) as **true**.

Prerequisites

You must have a valid Amazon Web Services developer account, and be signed up to use Amazon Kinesis. More information are available at [AWS Kinesis](#).

7.1. DEPENDENCIES

When using **aws2-kinesis** Red Hat build of Camel Spring Boot, add the following Maven dependency to your **pom.xml** to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-aws2-kinesis-starter</artifactId>
</dependency>
```

7.2. URI FORMAT

```
aws2-kinesis://stream-name[?options]
```

The stream needs to be created prior to it being used. You can append query options to the URI in the following format, **?options=value&option2=value&...**

7.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

7.3.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).

- in a configuration file (application.properties, *.yaml files, etc).
- directly in the Java code.

7.3.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

7.4. COMPONENT OPTIONS

The AWS Kinesis component supports 36 options, which are listed below.

Name	Description	Default	Type
cborEnabled (common)	This option will set the CBOR_ENABLED property during the execution.	true	boolean
configuration (common)	Component configuration.		Kinesis2Configuration
overrideEndpoint (common)	Set the need for overriding the endpoint. This option needs to be used in combination with uriEndpointOverride option.	false	boolean
region (common)	The region in which Kinesis Firehose client needs to work. When using this parameter, the configuration will expect the lowercase name of the region (for example ap-east-1) You'll need to use the name Region.EU_WEST_1.id(). Enum values: * ap-south-2 * ap-south-1		String

Name	Description	Default	Type
	* eu-south-1		
	* eu-south-2		
	* us-gov-east-1		
	* me-central-1		
	* il-central-1		
	* ca-central-1		
	* eu-central-1		
	* us-iso-west-1		
	* eu-central-2		
	* eu-isoe-west-1		
	* us-west-1		
	* us-west-2		
	* af-south-1		
	* eu-north-1		
	* eu-west-3		
	* eu-west-2		
	* eu-west-1		
	* ap-northeast-3		
	* ap-northeast-2		
	* ap-northeast-1		
	* me-south-1		
	* sa-east-1		
	* ap-east-1		
	* cn-north-1		
	* ca-west-1		
	* us-gov-west-1		
	* ap-southeast-1		
	* ap-southeast-2		
	* us-iso-east-1		
	* ap-southeast-3		
	* ap-southeast-4		

Name	Description * us-east-1 * us-east-2	Default	Type
	* cn-northwest-1 * us-isob-east-1 * aws-global * aws-cn-global * aws-us-gov-global * aws-iso-global * aws-iso-b-global		
uriEndpointOverride (common)	Set the overriding uri endpoint. This option needs to be used in combination with <code>overrideEndpoint</code> option.		String
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions (if possible) occurred while the Camel consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. Important: This is only possible if the 3rd party component allows Camel to be alerted if an exception was thrown. Some components handle this internally only, and therefore <code>bridgeErrorHandler</code> is not possible. In other situations we may improve the Camel component to hook into the 3rd party component and make this possible for future releases. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
iteratorType (consumer)	Defines where in the Kinesis stream to start getting records. Enum values: * AT_SEQUENCE_NUMBER * AFTER_SEQUENCE_NUMBER * TRIM_HORIZON * LATEST * AT_TIMESTAMP * null	TRIM_HORIZON	ShardIteratorType

Name	Description	Default	Type
maxResultsPerRequest (consumer)	Maximum number of records that will be fetched in each poll.	1	int
messageTimestamp (consumer)	The message timestamp to start polling from. Required if iteratorType is set to AT_TIMESTAMP.		String
sequenceNumber (consumer)	The sequence number to start polling from. Required if iteratorType is set to AFTER_SEQUENCE_NUMBER or AT_SEQUENCE_NUMBER.		String
shardClosed (consumer)	Define what will be the behavior in case of shard closed. Possible value are ignore, silent and fail. In case of ignore a WARN message will be logged once and the consumer will not process new messages until restarted, in case of silent there will be no logging and the consumer will not process new messages until restarted, in case of fail a ReachedClosedStateException will be thrown. Enum values: * ignore * fail * silent	ignore	Kinesis2ShardClosedStrategyEnum
shardId (consumer)	Defines which shardId in the Kinesis stream to get records from.		String
shardMonitorInterval (consumer (advanced))	The interval in milliseconds to wait between shard polling.	10000	long
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

Name	Description	Default	Type
amazonKinesisAsyncClient (advanced)	Autowired Supply a pre-constructed Amazon Kinesis async client to use for the KCL Consumer.		KinesisAsyncClient
amazonKinesisClient (advanced)	Autowired Amazon Kinesis client to use for all requests for this endpoint.		KinesisClient
applicationName (advanced)	Name of the KCL application. This defaults to the stream name.		String
asyncClient (advanced)	If we want to a KinesisAsyncClient instance set it to true.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
cloudWatchAsyncClient (advanced)	If we want to a KCL Consumer, we can pass an instance of CloudWatchAsyncClient.		CloudWatchAsyncClient
dynamoDbAsyncClient (advanced)	If we want to a KCL Consumer, we can pass an instance of DynamoDbAsyncClient.		DynamoDbAsyncClient
kclDisableCloudwatchMetricsExport (advanced)	If we want to use a KCL Consumer and disable the CloudWatch Metrics Export.	false	boolean
useKclConsumers (advanced)	If we want to a KCL Consumer set it to true.	false	boolean
healthCheckConsumerEnabled (health)	Used for enabling or disabling all consumer based health checks from this component.	true	boolean
healthCheckProducerEnabled (health)	Used for enabling or disabling all producer based health checks from this component. NOTE: Camel has by default disabled all producer based health-checks. You can turn on producer checks globally by setting camel.health.producersEnabled=true .	true	boolean
proxyHost (proxy)	To define a proxy host when instantiating the Kinesis client.		String

Name	Description	Default	Type
proxyPort (proxy)	To define a proxy port when instantiating the Kinesis client.		Integer
proxyProtocol (proxy)	To define a proxy protocol when instantiating the Kinesis client. Enum values: * HTTP * HTTPS	HTTPS	Protocol
accessKey (security)	Amazon AWS Access Key.		String
profileCredentialsName (security)	If using a profile credentials provider this parameter will set the profile name.		String
secretKey (security)	Amazon AWS Secret Key.		String
sessionToken (security)	Amazon AWS Session Token used when the user needs to assume a IAM role.		String
trustAllCertificates (security)	If we want to trust all certificates in case of overriding the endpoint.	false	boolean
useDefaultCredentialsProvider (security)	Set whether the Kinesis client should expect to load credentials through a default credentials provider or to expect static credentials to be passed in.	false	boolean
useProfileCredentialsProvider (security)	Set whether the Kinesis client should expect to load credentials through a profile credentials provider.	false	boolean
useSessionCredentials (security)	Set whether the Kinesis client should expect to use Session Credentials. This is useful in situation in which the user needs to assume a IAM role for doing operations in Kinesis.	false	boolean

7.5. ENDPOINT OPTIONS

The AWS Kinesis endpoint is configured using URI syntax:

```
aws2-kinesis:streamName
```

with the following path and query parameters:

7.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
streamName (common)	Required Name of the stream.		String

7.5.2. Query Parameters (50 parameters)

Name	Description	Default	Type
amazonKinesisClient (common)	Autowired Amazon Kinesis client to use for all requests for this endpoint.		KinesisClient
cborEnabled (common)	This option will set the CBOR_ENABLED property during the execution.	true	boolean
overrideEndpoint (common)	Set the need for overriding the endpoint. This option needs to be used in combination with uriEndpointOverride option.	false	boolean
proxyHost (common)	To define a proxy host when instantiating the Kinesis client.		String
proxyPort (common)	To define a proxy port when instantiating the Kinesis client.		Integer
proxyProtocol (common)	To define a proxy protocol when instantiating the Kinesis client. Enum values: • HTTP • HTTPS	HTTPS	Protocol
region (common)	The region in which Kinesis Firehose client needs to work. When using this parameter, the configuration will expect the lowercase name of the region (for example ap-east-1) You'll need to use the name Region.EU_WEST_1.id(). Enum values: • ap-south-2 • ap-south-1 • eu-south-1		String

Name	• eu-south-2 • us-gov-east-1 Description	Default	Type
	• me-central-1 • il-central-1 • ca-central-1 • eu-central-1 • us-iso-west-1 • eu-central-2 • eu-isoe-west-1 • us-west-1 • us-west-2 • af-south-1 • eu-north-1 • eu-west-3 • eu-west-2 • eu-west-1 • ap-northeast-3 • ap-northeast-2 • ap-northeast-1 • me-south-1 • sa-east-1 • ap-east-1 • cn-north-1 • ca-west-1 • us-gov-west-1 • ap-southeast-1 • ap-southeast-2 • us-iso-east-1 • ap-southeast-3 • ap-southeast-4 • us-east-1 • us-east-2 • cn-northwest-1		

Name	Description - us-isob-east-1 - aws-global	Default	Type
	- aws-cn-global - aws-us-gov-global - aws-iso-global - aws-iso-b-global		
trustAllCertificates (common)	If we want to trust all certificates in case of overriding the endpoint.	false	boolean
uriEndpointOverride (common)	Set the overriding uri endpoint. This option needs to be used in combination with overrideEndpoint option.		String
useDefaultCredentialsProvider (common)	Set whether the Kinesis client should expect to load credentials through a default credentials provider or to expect static credentials to be passed in.	false	boolean
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
iteratorType (consumer)	Defines where in the Kinesis stream to start getting records. Enum values: - AT_SEQUENCE_NUMBER - AFTER_SEQUENCE_NUMBER - TRIM_HORIZON - LATEST - AT_TIMESTAMP - null	TRIM_HORIZON	ShardIteratorType
maxResultsPerRequest (consumer)	Maximum number of records that will be fetched in each poll.	1	int

Name	Description	Default	Type
resumeStrategy (consumer)	Defines a resume strategy for AWS Kinesis. The default strategy reads the sequenceNumber if provided.	Kinesis UserC onfigur ationR esume Strate gy	KinesisResumeStr ategy
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean
sequenceNumber (consumer)	The sequence number to start polling from. Required if iteratorType is set to AFTER_SEQUENCE_NUMBER or AT_SEQUENCE_NUMBER.		String
shardClosed (consumer)	Define what will be the behavior in case of shard closed. Possible value are ignore, silent and fail. In case of ignore a message will be logged and the consumer will restart from the beginning, in case of silent there will be no logging and the consumer will start from the beginning, in case of fail a ReachedClosedStateException will be raised. Enum values: ● ignore ● fail ● silent	ignore	Kinesis2ShardClos edStrategyEnum
shardId (consumer)	Defines which shardId in the Kinesis stream to get records from.		String
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler

Name	Description	Default	Type
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: ● InOnly ● InOut ● InOptionalOut		ExchangePattern
pollStrategy (consumer (advanced))	A pluggable <code>org.apache.camel.PollingConsumerPollingStrategy</code> allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		PollingConsumerPollStrategy
shardMonitorInterval (consumer (advanced))	The interval in milliseconds to wait between shard polling.	10000	long
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
amazonKinesisAsyncClient (advanced)	Autowired Supply a pre-constructed Amazon Kinesis async client to use for the KCL Consumer.		KinesisAsyncClient
amazonKinesisClient (advanced)	Autowired Amazon Kinesis client to use for all requests for this endpoint.		KinesisClient
applicationName (advanced)	Name of the KCL application. This defaults to the stream name.		String
asyncClient (advanced)	If we want to a KinesisAsyncClient instance set it to true.	false	boolean
cloudWatchAsyncClient (advanced)	If we want to a KCL Consumer, we can pass an instance of CloudWatchAsyncClient.		CloudWatchAsyncClient

Name	Description	Default	Type
dynamoDbAsyncClient (advanced)	If we want to a KCL Consumer, we can pass an instance of DynamoDbAsyncClient.		DynamoDbAsyncClient
kclDisableCloudwatchMetricsExport (advanced)	If we want to use a KCL Consumer and disable the CloudWatch Metrics Export.	false	boolean
useKclConsumers (advanced)	If we want to a KCL Consumer set it to true.	false	boolean
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.		int
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.		int
delay (scheduler)	Milliseconds before the next poll.	500	long
greedy (scheduler)	If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts.	1000	long
repeatCount (scheduler)	Specifies a maximum limit of number of fires. So if you set it to 1, the scheduler will only fire once. If you set it to 5, it will only fire five times. A value of zero or negative means fire forever.	0	long

Name	Description	Default	Type
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that. Enum values: • TRACE • DEBUG • INFO • WARN • ERROR • OFF	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz component. Use value spring or quartz for built in scheduler.	none	Object
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for initialDelay and delay options. Enum values: • NANOSECONDS • MICROSECONDS • MILLISECONDS • SECONDS • MINUTES • HOURS • DAYS	MILLIS ECON DS	TimeUnit

Name	Description	Default	Type
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See <code>ScheduledExecutorService</code> in JDK for details.	true	boolean
accessKey (security)	Amazon AWS Access Key.		String
profileCredentialsName (security)	If using a profile credentials provider this parameter will set the profile name.		String
secretKey (security)	Amazon AWS Secret Key.		String
sessionToken (security)	Amazon AWS Session Token used when the user needs to assume a IAM role.		String
trustAllCertificates (security)	If we want to trust all certificates in case of overriding the endpoint.	false	boolean
useDefaultCredentialsProvider (security)	Set whether the Kinesis client should expect to load credentials through a default credentials provider or to expect static credentials to be passed in.	false	boolean
useProfileCredentialsProvider (security)	Set whether the Kinesis client should expect to load credentials through a profile credentials provider.	false	boolean
useSessionCredentials (security)	Set whether the Kinesis client should expect to use Session Credentials. This is useful in situation in which the user needs to assume a IAM role for doing operations in Kinesis.	false	boolean

Required Kinesis component options

You have to provide the **KinesisClient** in the Registry with proxies and relevant credentials configured.

7.6. MESSAGE HEADERS

Name	Description
CamelAwsKinesisSequenceNumber (common) Constant: SEQUENCE_NUMBER	The sequence number of the record as defined in PutRecord syntax .

Name	Description
CamelAwsKinesisApproximateArrivalTimestamp (common) Constant: APPROX_ARRIVAL_TIME	The time AWS assigned as the arrival time of the record.
CamelAwsKinesisPartitionKey (common) Constant: PARTITION_KEY	Identifies which shard in the stream the data record is assigned to.
CamelMessageTimestamp (common) Constant: MESSAGE_TIMESTAMP	The timestamp of the message.
CamelAwsKinesisShardId (common) Constant: SHARD_ID	The shard ID of the shard where the data record was place

7.7. USAGE

7.7.1. Batch Consumer

This component implements the Batch Consumer. This allows you for instance to know how many messages exists in this batch and for instance let the Aggregator aggregate this number of messages.

The consumer is able to consume either from a single specific shard or all available shards (multiple shards consumption) of Amazon Kinesis. Therefore, if you leave the 'shardId' property in the DSL configuration empty, then it'll consume all available shards otherwise only the specified shard corresponding to the shardId will be consumed.

7.7.2. Batch Producer

This component implements the Batch Producer. This allows you to send multiple messages in a single request to Amazon Kinesis. Messages with batch size more than 500 is allowed. Producer will split them into multiple requests.

The batch type needs to implement the **Iterable** interface. For example, it can be a **List**, **Set** or any other collection type. The message type can be one or more of types **byte[]**, **ByteBuffer**, UTF-8 **String**, or **InputStream**. Other types are not supported.

7.7.3. Static credentials, Default Credential Provider and Profile Credentials Provider

You have the possibility of avoiding the usage of explicit static credentials, by specifying the `useDefaultCredentialsProvider` option and set it to true.

The order of evaluation for Default Credentials Provider is the following:

- Java system properties - **aws.accessKeyId** and **aws.secretAccessKey**
- Environment variables - **AWS_ACCESS_KEY_ID** and **AWS_SECRET_ACCESS_KEY**.

- Web Identity Token from AWS STS.
- The shared credentials and config files.
- Amazon ECS container credentials - loaded from the Amazon ECS if the environment variable **AWS_CONTAINER_CREDENTIALS_RELATIVE_URI** is set.
- Amazon EC2 Instance profile credentials.

You have also the possibility of using Profile Credentials Provider, by specifying the **useProfileCredentialsProvider** option to true and **profileCredentialsName** to the profile name.

Only one of static, default and profile credentials could be used at the same time.

For more information see [AWS credentials documentation](#).

7.7.4. AmazonKinesis configuration

You then have to reference the **KinesisClient** in the **amazonKinesisClient** URI option.

```
from("aws2-kinesis://mykinesisstream?amazonKinesisClient=#kinesisClient")
.to("log:out?showAll=true");
```

7.7.5. Providing AWS Credentials

It is recommended that the credentials are obtained by using the [DefaultAWSCredentialsProviderChain](#) that is the default when creating a new ClientConfiguration instance, however, a different [AWSCredentialsProvider](#) can be specified when calling `createClient(...)`.

7.7.6. AWS Kinesis KCL Consumer

The component supports also the KCL (Kinesis Client Library) for consuming from a Kinesis Data Stream. To enable this feature, set the three different parameters in your endpoint and set the region:

```
from("aws2-kinesis://mykinesisstream?
asyncClient=true&useDefaultCredentialsProvider=true&useKclConsumers=true&region=myregion")
.to("log:out?showAll=true");
```

This feature makes it possible to automatically checkpoint the Shard Iterations by combining the usage of KCL, DynamoDB Table and CloudWatch alarms. This works out of the box, by simply using your AWS Credentials.

NOTE

AWS Kinesis consumer with KCL needs approximately 60-70 seconds to startup to prepare everything, for example, listing the shards, creating/querying the Lease table on Dynamo DB.

7.8. SPRING BOOT AUTO-CONFIGURATION

The component supports 58 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.aws2-kinesis-firehose.access-key</code>	Amazon AWS Access Key.		String
<code>camel.component.aws2-kinesis-firehose.amazon-kinesis-firehose-client</code>	Amazon Kinesis Firehose client to use for all requests for this endpoint. The option is a <code>software.amazon.awssdk.services.firehose.FirehoseClient</code> type.		FirehoseClient
<code>camel.component.aws2-kinesis-firehose.autowired-enabled</code>	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
<code>camel.component.aws2-kinesis-firehose.cbor-enabled</code>	This option will set the <code>CBOR_ENABLED</code> property during the execution.	true	Boolean
<code>camel.component.aws2-kinesis-firehose.configuration</code>	Component configuration. The option is a <code>org.apache.camel.component.aws2.firehose.KinesisFirehose2Configuration</code> type.		KinesisFirehose2Configuration
<code>camel.component.aws2-kinesis-firehose.enabled</code>	Whether to enable auto configuration of the <code>aws2-kinesis-firehose</code> component. This is enabled by default.		Boolean
<code>camel.component.aws2-kinesis-firehose.lazy-start-producer</code>	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
<code>camel.component.aws2-kinesis-firehose.operation</code>	The operation to do in case the user don't want to send only a record.		KinesisFirehose2Operations

Name	Description	Default	Type
<code>camel.component.aws2-kinesis-firehose.override-endpoint</code>	Set the need for overriding the endpoint. This option needs to be used in combination with <code>uriEndpointOverride</code> option.	false	Boolean
<code>camel.component.aws2-kinesis-firehose.profile-credentials-name</code>	If using a profile credentials provider this parameter will set the profile name.		String
<code>camel.component.aws2-kinesis-firehose.proxy-host</code>	To define a proxy host when instantiating the Kinesis Firehose client.		String
<code>camel.component.aws2-kinesis-firehose.proxy-port</code>	To define a proxy port when instantiating the Kinesis Firehose client.		Integer
<code>camel.component.aws2-kinesis-firehose.proxy-protocol</code>	To define a proxy protocol when instantiating the Kinesis Firehose client.		Protocol
<code>camel.component.aws2-kinesis-firehose.region</code>	The region in which Kinesis Firehose client needs to work. When using this parameter, the configuration will expect the lowercase name of the region (for example <code>ap-east-1</code>) You'll need to use the name <code>Region.EU_WEST_1.id()</code> .		String
<code>camel.component.aws2-kinesis-firehose.secret-key</code>	Amazon AWS Secret Key.		String
<code>camel.component.aws2-kinesis-firehose.session-token</code>	Amazon AWS Session Token used when the user needs to assume a IAM role.		String
<code>camel.component.aws2-kinesis-firehose.trust-all-certificates</code>	If we want to trust all certificates in case of overriding the endpoint.	false	Boolean

Name	Description	Default	Type
<code>camel.component.aws2-kinesis-firehose.uri-endpoint-override</code>	Set the overriding uri endpoint. This option needs to be used in combination with <code>overrideEndpoint</code> option.		String
<code>camel.component.aws2-kinesis-firehose.use-default-credentials-provider</code>	Set whether the Kinesis Firehose client should expect to load credentials through a default credentials provider or to expect static credentials to be passed in.	false	Boolean
<code>camel.component.aws2-kinesis-firehose.use-profile-credentials-provider</code>	Set whether the Kinesis Firehose client should expect to load credentials through a profile credentials provider.	false	Boolean
<code>camel.component.aws2-kinesis-firehose.use-session-credentials</code>	Set whether the Kinesis Firehose client should expect to use Session Credentials. This is useful in situation in which the user needs to assume a IAM role for doing operations in Kinesis Firehose.	false	Boolean
<code>camel.component.aws2-kinesis.access-key</code>	Amazon AWS Access Key.		String
<code>*camel.component.aws2-kinesis.amazon-kinesis-async-client</code>	Supply a pre-constructed Amazon Kinesis async client to use for the KCL Consumer. The option is a <code>software.amazon.awssdk.services.kinesis.KinesisAsyncClient</code> type.		KinesisAsyncClient
<code>camel.component.aws2-kinesis.amazon-kinesis-client</code>	Amazon Kinesis client to use for all requests for this endpoint. The option is a <code>software.amazon.awssdk.services.kinesis.KinesisClient</code> type.		KinesisClient
<code>camel.component.aws2-kinesis.application-name</code>	Name of the KCL application. This defaults to the stream name.		String

Name	Description	Default	Type
<code>camel.component.aws2-kinesis.async-client</code>	If we want to a <code>KinesisAsyncClient</code> instance set it to true.	false	Boolean
<code>camel.component.aws2-kinesis.autowired-enabled</code>	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
<code>camel.component.aws2-kinesis.bridge-error-handler</code>	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
<code>camel.component.aws2-kinesis.cbor-enabled</code>	This option will set the <code>CBOR_ENABLED</code> property during the execution.	true	Boolean
<code>camel.component.aws2-kinesis.cloud-watch-async-client</code>	If we want to a KCL Consumer, we can pass an instance of <code>CloudWatchAsyncClient</code> . The option is a <code>software.amazon.awssdk.services.cloudwatch.CloudWatchAsyncClient</code> type.		<code>CloudWatchAsyncClient</code>
<code>camel.component.aws2-kinesis.configuration</code>	Component configuration. The option is a <code>org.apache.camel.component.aws2.kinesis.Kinesis2Configuration</code> type.		<code>Kinesis2Configuration</code>
<code>camel.component.aws2-kinesis.dynamodb-async-client</code>	If we want to a KCL Consumer, we can pass an instance of <code>DynamoDbAsyncClient</code> . The option is a <code>software.amazon.awssdk.services.dynamodb.DynamoDbAsyncClient</code> type.		<code>DynamoDbAsyncClient</code>
<code>camel.component.aws2-kinesis.enabled</code>	Whether to enable auto configuration of the <code>aws2-kinesis</code> component. This is enabled by default.		Boolean

Name	Description	Default	Type
<code>camel.component.aws2-kinesis.health-check-consumer-enabled</code>	Used for enabling or disabling all consumer based health checks from this component.	true	Boolean
<code>camel.component.aws2-kinesis.health-check-producer-enabled</code>	Used for enabling or disabling all producer based health checks from this component. Notice: Camel has by default disabled all producer based health-checks. You can turn on producer checks globally by setting camel.health.producersEnabled=true .	true	Boolean
<code>camel.component.aws2-kinesis.iterator-type</code>	Defines where in the Kinesis stream to start getting records.		ShardIteratorType
<code>camel.component.aws2-kinesis.kcl-disable-cloudwatch-metrics-export</code>	If we want to use a KCL Consumer and disable the CloudWatch Metrics Export.	false	Boolean
<code>camel.component.aws2-kinesis.lazy-start-producer</code>	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
<code>camel.component.aws2-kinesis.max-results-per-request</code>	Maximum number of records that will be fetched in each poll.	1	Integer

Name	Description	Default	Type
<code>camel.component.aws2-kinesis.message-timestamp</code>	The message timestamp to start polling from. Required if <code>iteratorType</code> is set to <code>AT_TIMESTAMP</code> .		String
<code>camel.component.aws2-kinesis.override-endpoint</code>	Set the need for overriding the endpoint. This option needs to be used in combination with <code>uriEndpointOverride</code> option.	false	Boolean
<code>camel.component.aws2-kinesis.profile-credentials-name</code>	If using a profile credentials provider this parameter will set the profile name.		String
<code>camel.component.aws2-kinesis.proxy-host</code>	To define a proxy host when instantiating the Kinesis client.		String
<code>camel.component.aws2-kinesis.proxy-port</code>	To define a proxy port when instantiating the Kinesis client.		Integer
<code>camel.component.aws2-kinesis.proxy-protocol</code>	To define a proxy protocol when instantiating the Kinesis client.		Protocol
<code>camel.component.aws2-kinesis.region</code>	The region in which Kinesis Firehose client needs to work. When using this parameter, the configuration will expect the lowercase name of the region (for example <code>ap-east-1</code>) You'll need to use the name <code>Region.EU_WEST_1.id()</code> .		String
<code>camel.component.aws2-kinesis.secret-key</code>	Amazon AWS Secret Key.		String
<code>camel.component.aws2-kinesis.sequence-number</code>	The sequence number to start polling from. Required if <code>iteratorType</code> is set to <code>AFTER_SEQUENCE_NUMBER</code> or <code>AT_SEQUENCE_NUMBER</code> .		String

Name	Description	Default	Type
<code>camel.component.aws2-kinesis.session-token</code>	Amazon AWS Session Token used when the user needs to assume a IAM role.		String
<code>camel.component.aws2-kinesis.shard-closed</code>	Define what will be the behavior in case of shard closed. Possible value are ignore, silent and fail. In case of ignore a message will be logged and the consumer will restart from the beginning, in case of silent there will be no logging and the consumer will start from the beginning, in case of fail a <code>ReachedClosedStateException</code> will be raised.		<code>Kinesis2ShardClosedStrategyEnum</code>
<code>camel.component.aws2-kinesis.shard-id</code>	Defines which shardId in the Kinesis stream to get records from.		String
<code>*camel.component.aws2-kinesis.shard-monitor-interval</code>	The interval in milliseconds to wait between shard polling.	10000	Long
<code>camel.component.aws2-kinesis.trust-all-certificates</code>	If we want to trust all certificates in case of overriding the endpoint.	false	Boolean
<code>camel.component.aws2-kinesis.uri-endpoint-override</code>	Set the overriding uri endpoint. This option needs to be used in combination with <code>overrideEndpoint</code> option.		String
<code>camel.component.aws2-kinesis.use-default-credentials-provider</code>	Set whether the Kinesis client should expect to load credentials through a default credentials provider or to expect static credentials to be passed in.	false	Boolean
<code>camel.component.aws2-kinesis.use-profile-credentials-provider</code>	Set whether the Kinesis client should expect to load credentials through a profile credentials provider.	false	Boolean
<code>camel.component.aws2-kinesis.use-session-credentials</code>	Set whether the Kinesis client should expect to use Session Credentials. This is useful in situation in which the user needs to assume a IAM role for doing operations in Kinesis.	false	Boolean

Name	Description	Default	Type
------	-------------	---------	------

CHAPTER 8. AWS 2 LAMBDA

Only producer is supported

The AWS2 Lambda component supports create, get, list, delete and invoke [AWS Lambda](#) functions.

Prerequisites

You must have a valid Amazon Web Services developer account, and be signed up to use Amazon Lambda. More information is available at [AWS Lambda](#).

When creating a Lambda function, you need to specify a IAM role which has at least the AWSLambdaBasicExecuteRole policy attached.

8.1. DEPENDENCIES

When using **aws2-lambda** with Red Hat build of Camel Spring Boot, add the following Maven dependency to your **pom.xml** to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-aws2-lambda-starter</artifactId>
</dependency>
```

8.2. URI FORMAT

```
aws2-lambda://functionName[?options]
```

You can append query options to the URI in the following format, **options=value&option2=value&...**

8.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

8.3.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).

- directly in the Java code.

8.3.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

8.4. COMPONENT OPTIONS

The AWS Lambda component supports 16 options, which are listed below.

Name	Description	Default	Type
configuration (producer)	Component configuration.		Lambda2Configuration
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

Name	Description	Default	Type
operation (producer)	The operation to perform. It can be listFunctions, getFunction, createFunction, deleteFunction or invokeFunction. Enum values: • listFunctions • getFunction • createAlias • deleteAlias • getAlias • listAliases • createFunction • deleteFunction • invokeFunction • updateFunction • createEventSourceMapping • deleteEventSourceMapping • listEventSourceMapping • listTags • tagResource • untagResource • publishVersion • listVersions	invokeFunction	Lambda2Operations
overrideEndpoint (producer)	Set the need for overriding the endpoint. This option needs to be used in combination with uriEndpointOverride option.	false	boolean
pojoRequest (producer)	If we want to use a POJO request as body or not.	false	boolean
region (producer)	The region in which Lambda client needs to work. When using this parameter, the configuration will expect the lowercase name of the region (for example ap-east-1) You'll need to use the name Region.EU_WEST_1.id().		String

Name	Description	Default	Type
trustAllCertificates (producer)	If we want to trust all certificates in case of overriding the endpoint.	false	boolean
uriEndpointOverride (producer)	Set the overriding uri endpoint. This option needs to be used in combination with <code>overrideEndpoint</code> option.		String
useDefaultCredentialsProvider (producer)	Set whether the Lambda client should expect to load credentials through a default credentials provider or to expect static credentials to be passed in.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
awsLambdaClient (advanced)	Autowired To use a existing configured <code>AwsLambdaClient</code> as client.		<code>LambdaClient</code>
proxyHost (proxy)	To define a proxy host when instantiating the Lambda client.		String
proxyPort (proxy)	To define a proxy port when instantiating the Lambda client.		Integer
proxyProtocol (proxy)	To define a proxy protocol when instantiating the Lambda client. Enum values: • HTTP • HTTPS	HTTPS	Protocol
accessKey (security)	Amazon AWS Access Key.		String
secretKey (security)	Amazon AWS Secret Key.		String

8.5. ENDPOINT OPTIONS

The AWS Lambda endpoint is configured using URI syntax:

`aws2-lambda:function`

with the following path and query parameters:

8.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
function (producer)	Required Name of the Lambda function.		String

8.5.2. Query Parameters (14 parameters)

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

Name	Description	Default	Type
operation (producer)	The operation to perform. It can be listFunctions, getFunction, createFunction, deleteFunction or invokeFunction. Enum values: • listFunctions • getFunction • createAlias • deleteAlias • getAlias • listAliases • createFunction • deleteFunction • invokeFunction • updateFunction • createEventSourceMapping • deleteEventSourceMapping • listEventSourceMapping • listTags • tagResource • untagResource • publishVersion • listVersions	invokeFunction	Lambda2Operations
overrideEndpoint (producer)	Set the need for overriding the endpoint. This option needs to be used in combination with uriEndpointOverride option.	false	boolean
pojoRequest (producer)	If we want to use a POJO request as body or not.	false	boolean
region (producer)	The region in which Lambda client needs to work. When using this parameter, the configuration will expect the lowercase name of the region (for example ap-east-1) You'll need to use the name Region.EU_WEST_1.id().		String

Name	Description	Default	Type
trustAllCertificates (producer)	If we want to trust all certificates in case of overriding the endpoint.	false	boolean
uriEndpointOverride (producer)	Set the overriding uri endpoint. This option needs to be used in combination with <code>overrideEndpoint</code> option.		String
useDefaultCredentialsProvider (producer)	Set whether the Lambda client should expect to load credentials through a default credentials provider or to expect static credentials to be passed in.	false	boolean
awsLambdaClient (advanced)	Autowired To use an existing configured <code>AwsLambdaClient</code> as client.		<code>LambdaClient</code>
proxyHost (proxy)	To define a proxy host when instantiating the Lambda client.		String
proxyPort (proxy)	To define a proxy port when instantiating the Lambda client.		Integer
proxyProtocol (proxy)	To define a proxy protocol when instantiating the Lambda client. Enum values: • HTTP • HTTPS	HTTPS	Protocol
accessKey (security)	Amazon AWS Access Key.		String
secretKey (security)	Amazon AWS Secret Key.		String

Required Lambda component options

You have to provide the `awsLambdaClient` in the Registry or your `accessKey` and `secretKey` to access the [Amazon Lambda](#) service..

8.6. USAGE

8.6.1. Static credentials vs Default Credential Provider

You have the possibility of avoiding the usage of explicit static credentials, by specifying the `useDefaultCredentialsProvider` option and set it to true.

- Java system properties - `aws.accessKeyId` and `aws.secretKey`

- Environment variables - AWS_ACCESS_KEY_ID and AWS_SECRET_ACCESS_KEY.
- Web Identity Token from AWS STS.
- The shared credentials and config files.
- Amazon ECS container credentials - loaded from the Amazon ECS if the environment variable AWS_CONTAINER_CREDENTIALS_RELATIVE_URI is set.
- Amazon EC2 Instance profile credentials.

For more information about this you can look at [AWS credentials documentation](#)

8.6.2. Message headers evaluated by the Lambda producer

Operation	Header	Type	Description	Required
All	CamelAwsLambdaOperation	String	The operation we want to perform. Override operation passed as query parameter	Yes
createFunction	CamelAwsLambdaS3Bucket	String	Amazon S3 bucket name where the .zip file containing your deployment package is stored. This bucket must reside in the same AWS region where you are creating the Lambda function.	No
createFunction	CamelAwsLambdaS3Key	String	The Amazon S3 object (the deployment package) key name you want to upload.	No
createFunction	CamelAwsLambdaS3ObjectVersion	String	The Amazon S3 object (the deployment package) version you want to upload.	No
createFunction	CamelAwsLambdaZipFile	String	The local path of the zip file (the deployment package). Content of zip file can also be put in Message body.	No

Operation	Header	Type	Description	Required
createFunction	CamelAwsLambdaRole	String	The Amazon Resource Name (ARN) of the IAM role that Lambda assumes when it executes your function to access any other Amazon Web Services (AWS) resources.	Yes
createFunction	CamelAwsLambdaRuntime	String	The runtime environment for the Lambda function you are uploading. (nodejs, nodejs4.3, nodejs6.10, java8, python2.7, python3.6, dotnetcore1.0, nodejs4.3-edge)	Yes
createFunction	CamelAwsLambdaHandler	String	The function within your code that Lambda calls to begin execution. For Node.js, it is the module-name.export value in your function. For Java, it can be package.class-name::handler or package.class-name.	Yes
createFunction	CamelAwsLambdaDescription	String	The user-provided description.	No
createFunction	CamelAwsLambdaTargetArn	String	The parent object that contains the target ARN (Amazon Resource Name) of an Amazon SQS queue or Amazon SNS topic.	No
createFunction	CamelAwsLambdaMemorySize	Integer	The memory size, in MB, you configured for the function. Must be a multiple of 64 MB.	No

Operation	Header	Type	Description	Required
createFunction	CamelAwsLambdaKMSKeyArn	String	The Amazon Resource Name (ARN) of the KMS key used to encrypt your function's environment variables. If not provided, AWS Lambda will use a default service key.	No
createFunction	CamelAwsLambdaPublish	Boolean	This boolean parameter can be used to request AWS Lambda to create the Lambda function and publish a version as an atomic operation.	No
createFunction	CamelAwsLambdaTimeout	Integer	The function execution time at which Lambda should terminate the function. The default is 3 seconds.	No
createFunction	CamelAwsLambdaTracingConfig	String	Your function's tracing settings (Active or PassThrough).	No
createFunction	CamelAwsLambdaEnvironmentVariables	Map<String, String>	The key-value pairs that represent your environment's configuration settings.	No
createFunction	CamelAwsLambdaEnvironmentTags	Map<String, String>	The list of tags (key-value pairs) assigned to the new function.	No
createFunction	CamelAwsLambdaSecurityGroupIds	List<String>	If your Lambda function accesses resources in a VPC, a list of one or more security groups IDs in your VPC.	No
createFunction	CamelAwsLambdaSubnetIds	List<String>	If your Lambda function accesses resources in a VPC, a list of one or more subnet IDs in your VPC.	No
createAlias	CamelAwsLambdaFunctionVersion	String	The function version to set in the alias	Yes

Operation	Header	Type	Description	Required
-----------	--------	------	-------------	----------

createAlias	CamelAwsLambdaAliasFunctionName	String	The function name to set in the alias	Yes
createAlias	CamelAwsLambdaAliasFunctionDescription	String	The function description to set in the alias	No
deleteAlias	CamelAwsLambdaAliasFunctionName	String	The function name of the alias	Yes
getAlias	CamelAwsLambdaAliasFunctionName	String	The function name of the alias	Yes
listAliases	CamelAwsLambdaFunctionVersion	String	The function version to set in the alias	No

8.7. LIST OF AVAILABLE OPERATIONS

- listFunctions
- getFunction
- createFunction
- deleteFunction
- invokeFunction
- updateFunction
- createEventSourceMapping
- deleteEventSourceMapping
- listEventSourceMapping
- listTags
- tagResource
- untagResource
- publishVersion
- listVersions

- createAlias
- deleteAlias
- getAlias
- listAliases

8.8. EXAMPLES

8.8.1. Producer Example

To have a full understanding of how the component works, you may have a look at these [integration tests](#).

8.8.2. Producer Examples

- CreateFunction: this operation will create a function for you in AWS Lambda

```
from("direct:createFunction").to("aws2-lambda://GetHelloWithName?
operation=createFunction").to("mock:result");
```

and by sending

```
template.send("direct:createFunction", ExchangePattern.InOut, new Processor() {
    @Override
    public void process(Exchange exchange) throws Exception {
        exchange.getIn().setHeader(Lambda2Constants.RUNTIME, "nodejs6.10");
        exchange.getIn().setHeader(Lambda2Constants.HANDLER, "GetHelloWithName.handler");
        exchange.getIn().setHeader(Lambda2Constants.DESRIPTION, "Hello with node.js on
Lambda");
        exchange.getIn().setHeader(Lambda2Constants.ROLE,
            "arn:aws:iam::643534317684:role/lambda-execution-role");
        ClassLoader classLoader = getClass().getClassLoader();
        File file = new File(
            classLoader

.getResource("org/apache/camel/component/aws2/lambda/function/node/GetHelloWithName.zip")
            .getFile());
        FileInputStream inputStream = new FileInputStream(file);
        exchange.getIn().setBody(inputStream);
    }
});
```

8.9. USING A POJO AS BODY

Sometimes build an AWS Request can be complex, because of multiple options. We introduce the possibility to use a POJO as body. In AWS Lambda there are multiple operations you can submit, as an example for Get Function request, you can do something like:

```
from("direct:getFunction")
    .setBody(GetFunctionRequest.builder().functionName("test").build())
    .to("aws2-lambda://GetHelloWithName?
```

```
awsLambdaClient=#awsLambdaClient&operation=getFunction&pojoRequest=true")
```

In this way you'll pass the request directly without the need of passing headers and options specifically related to this operation.

8.10. DEPENDENCIES

Maven users will need to add the following dependency to their pom.xml.

pom.xml

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-aws2-lambda</artifactId>
  <version>${camel-version}</version>
</dependency>
```

where **{camel-version}** must be replaced by the actual version of Camel.

8.11. SPRING BOOT AUTO-CONFIGURATION

The component supports 17 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.aws2-lambda.access-key</code>	Amazon AWS Access Key.		String
<code>camel.component.aws2-lambda.autowired-enabled</code>	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
<code>camel.component.aws2-lambda.aws-lambda-client</code>	To use a existing configured <code>AwsLambdaClient</code> as client. The option is a <code>software.amazon.awssdk.services.lambda.LambdaClient</code> type.		<code>LambdaClient</code>
<code>camel.component.aws2-lambda.configuration</code>	Component configuration. The option is a <code>org.apache.camel.component.aws2.lambda.Lambda2Configuration</code> type.		<code>Lambda2Configuration</code>

Name	Description	Default	Type
<code>camel.component.aws2-lambda.enabled</code>	Whether to enable auto configuration of the aws2-lambda component. This is enabled by default.		Boolean
<code>camel.component.aws2-lambda.lazy-start-producer</code>	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
<code>camel.component.aws2-lambda.operation</code>	The operation to perform. It can be listFunctions, getFunction, createFunction, deleteFunction or invokeFunction.		Lambda2Operations
<code>camel.component.aws2-lambda.override-endpoint</code>	Set the need for overriding the endpoint. This option needs to be used in combination with uriEndpointOverride option.	false	Boolean
<code>camel.component.aws2-lambda.pojo-request</code>	If we want to use a POJO request as body or not.	false	Boolean
<code>camel.component.aws2-lambda.proxy-host</code>	To define a proxy host when instantiating the Lambda client.		String
<code>camel.component.aws2-lambda.proxy-port</code>	To define a proxy port when instantiating the Lambda client.		Integer
<code>camel.component.aws2-lambda.proxy-protocol</code>	To define a proxy protocol when instantiating the Lambda client.		Protocol

Name	Description	Default	Type
<code>camel.component.aws2-lambda.region</code>	The region in which Lambda client needs to work. When using this parameter, the configuration will expect the lowercase name of the region (for example ap-east-1) You'll need to use the name <code>Region.EU_WEST_1.id()</code> .		String
<code>camel.component.aws2-lambda.secret-key</code>	Amazon AWS Secret Key.		String
<code>camel.component.aws2-lambda.trust-all-certificates</code>	If we want to trust all certificates in case of overriding the endpoint.	false	Boolean
<code>camel.component.aws2-lambda.uri-endpoint-override</code>	Set the overriding uri endpoint. This option needs to be used in combination with <code>overrideEndpoint</code> option.		String
<code>camel.component.aws2-lambda.use-default-credentials-provider</code>	Set whether the Lambda client should expect to load credentials through a default credentials provider or to expect static credentials to be passed in.	false	Boolean

CHAPTER 9. AWS S3 STORAGE SERVICE

Both producer and consumer are supported

The AWS2 S3 component supports storing and retrieving objects from/to [Amazon's S3](#) service.

Prerequisites

You must have a valid Amazon Web Services developer account, and be signed up to use Amazon S3. More information is available at link:<https://aws.amazon.com/s3> [Amazon S3].

9.1. DEPENDENCIES

When using **aws2-s3** with Red Hat build of Camel Spring Boot, add the following Maven dependency to your **pom.xml** to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-aws2-s3-starter</artifactId>
</dependency>
```

9.2. URI FORMAT

```
aws2-s3://bucketNameOrArn[?options]
```

The bucket will be created if it don't already exists. You can append query options to the URI in the following format,

options=value&option2=value&...

9.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

9.3.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).

- directly in the Java code.

9.3.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

9.4. COMPONENT OPTIONS

The AWS S3 Storage Service component supports 50 options, which are listed below.

Name	Description	Default	Type
amazonS3Client (common)	Autowired Reference to a <code>com.amazonaws.services.s3.AmazonS3</code> in the registry.		S3Client
amazonS3Presigner (common)	Autowired An S3 Presigner for Request, used mainly in <code>createDownloadLink</code> operation.		S3Presigner
autoCreateBucket (common)	Setting the autocreation of the S3 bucket <code>bucketName</code> . This will apply also in case of <code>moveAfterRead</code> option enabled and it will create the <code>destinationBucket</code> if it doesn't exist already.	false	boolean
configuration (common)	The component configuration.		AWS2S3Configuration
overrideEndpoint (common)	Set the need for overriding the endpoint. This option needs to be used in combination with <code>uriEndpointOverride</code> option.	false	boolean
pojoRequest (common)	If we want to use a POJO request as body or not.	false	boolean

Name	Description	Default	Type
policy (common)	The policy for this queue to set in the <code>com.amazonaws.services.s3.AmazonS3#setBucketPolicy()</code> method.		String
proxyHost (common)	To define a proxy host when instantiating the SQS client.		String
proxyPort (common)	Specify a proxy port to be used inside the client definition.		Integer
proxyProtocol (common)	To define a proxy protocol when instantiating the S3 client. Enum values: • HTTP • HTTPS	HTTPS	Protocol
region (common)	The region in which S3 client needs to work. When using this parameter, the configuration will expect the lowercase name of the region (for example <code>ap-east-1</code>) You'll need to use the name <code>Region.EU_WEST_1.id()</code> .		String
trustAllCertificates (common)	If we want to trust all certificates in case of overriding the endpoint.	false	boolean
uriEndpointOverride (common)	Set the overriding uri endpoint. This option needs to be used in combination with <code>overrideEndpoint</code> option.		String
useDefaultCredentialsProvider (common)	Set whether the S3 client should expect to load credentials through a default credentials provider or to expect static credentials to be passed in.	false	boolean
customerAlgorithm (common (advanced))	Define the customer algorithm to use in case <code>CustomerKey</code> is enabled.		String
customerKeyId (common (advanced))	Define the id of Customer key to use in case <code>CustomerKey</code> is enabled.		String
customerKeyMD5 (common (advanced))	Define the MD5 of Customer key to use in case <code>CustomerKey</code> is enabled.		String

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
deleteAfterRead (consumer)	Delete objects from S3 after they have been retrieved. The delete is only performed if the Exchange is committed. If a rollback occurs, the object is not deleted. If this option is false, then the same objects will be retrieve over and over again on the polls. Therefore you need to use the Idempotent Consumer EIP in the route to filter out duplicates. You can filter using the <code>AWS2S3Constants#BUCKET_NAME</code> and <code>AWS2S3Constants#KEY</code> headers, or only the <code>AWS2S3Constants#KEY</code> header.	true	boolean
delimiter (consumer)	The delimiter which is used in the <code>com.amazonaws.services.s3.model.ListObjectsRequest</code> to only consume objects we are interested in.		String
destinationBucket (consumer)	Define the destination bucket where an object must be moved when <code>moveAfterRead</code> is set to true.		String
destinationBucketPrefix (consumer)	Define the destination bucket prefix to use when an object must be moved and <code>moveAfterRead</code> is set to true.		String
destinationBucketSuffix (consumer)	Define the destination bucket suffix to use when an object must be moved and <code>moveAfterRead</code> is set to true.		String
doneFileName (consumer)	If provided, Camel will only consume files if a done file exists.		String
fileName (consumer)	To get the object from the bucket with the given file name.		String
ignoreBody (consumer)	If it is true, the S3 Object Body will be ignored completely, if it is set to false the S3 Object will be put in the body. Setting this to true, will override any behavior defined by <code>includeBody</code> option.	false	boolean

Name	Description	Default	Type
includeBody (consumer)	If it is true, the S3Object exchange will be consumed and put into the body and closed. If false the S3Object stream will be put raw into the body and the headers will be set with the S3 object metadata. This option is strongly related to autocloseBody option. In case of setting includeBody to true because the S3Object stream will be consumed then it will also be closed, while in case of includeBody false then it will be up to the caller to close the S3Object stream. However setting autocloseBody to true when includeBody is false it will schedule to close the S3Object stream automatically on exchange completion.	true	boolean
includeFolders (consumer)	If it is true, the folders/directories will be consumed. If it is false, they will be ignored, and Exchanges will not be created for those.	true	boolean
moveAfterRead (consumer)	Move objects from S3 bucket to a different bucket after they have been retrieved. To accomplish the operation the destinationBucket option must be set. The copy bucket operation is only performed if the Exchange is committed. If a rollback occurs, the object is not moved.	false	boolean
prefix (consumer)	The prefix which is used in the com.amazonaws.services.s3.model.ListObjectsRequest to only consume objects we are interested in.		String
autocloseBody (consumer (advanced))	If this option is true and includeBody is false, then the S3Object.close() method will be called on exchange completion. This option is strongly related to includeBody option. In case of setting includeBody to false and autocloseBody to false, it will be up to the caller to close the S3Object stream. Setting autocloseBody to true, will close the S3Object stream automatically.	true	boolean
batchMessageNumber (producer)	The number of messages composing a batch in streaming upload mode.	10	int
batchSize (producer)	The batch size (in bytes) in streaming upload mode.	100000	int
deleteAfterWrite (producer)	Delete file object after the S3 file has been uploaded.	false	boolean

Name	Description	Default	Type
keyName (producer)	Setting the key name for an element in the bucket through endpoint parameter.		String
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
multiPartUpload (producer)	If it is true, camel will upload the file with multi part format, the part size is decided by the option of partSize.	false	boolean
namingStrategy (producer)	The naming strategy to use in streaming upload mode. Enum values: ● progressive ● random	progressive	AWSS3NamingStrategyEnum
operation (producer)	The operation to do in case the user don't want to do only an upload. Enum values: ● copyObject ● listObjects ● deleteObject ● deleteBucket ● listBuckets ● getObject ● getObjectRange ● createDownloadLink		AWS2S3Operations

Name	Description	Default	Type
partSize (producer)	Setup the partSize which is used in multi part upload, the default size is 25M.	26214400	long
restartingPolicy (producer)	The restarting policy to use in streaming upload mode. Enum values: ● override ● lastPart	override	AWSS3RestartingPolicyEnum
storageClass (producer)	The storage class to set in the <code>com.amazonaws.services.s3.model.PutObjectRequest</code> request.		String
streamingUploadMode (producer)	When stream mode is true the upload to bucket will be done in streaming.	false	boolean
streamingUploadTimeout (producer)	While streaming upload mode is true, this option set the timeout to complete upload.		long
awsKMSKeyId (producer (advanced))	Define the id of KMS key to use in case KMS is enabled.		String
useAwsKMS (producer (advanced))	Define if KMS must be used or not.	false	boolean
useCustomerKey (producer (advanced))	Define if Customer Key must be used or not.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
accessKey (security)	Amazon AWS Access Key.		String
secretKey (security)	Amazon AWS Secret Key.		String

9.5. ENDPOINT OPTIONS

The AWS S3 Storage Service endpoint is configured using URI syntax:

```
aws2-s3://bucketNameOrArn
```

with the following path and query parameters:

9.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
bucketNameOrArn (common)	Required Bucket name or ARN.		String

9.5.2. Query Parameters (68 parameters)

Name	Description	Default	Type
amazonS3Client (common)	Autowired Reference to a <code>com.amazonaws.services.s3.AmazonS3</code> in the registry.		S3Client
amazonS3Presigner (common)	Autowired An S3 Presigner for Request, used mainly in <code>createDownloadLink</code> operation.		S3Presigner
autoCreateBucket (common)	Setting the autocreation of the S3 bucket <code>bucketName</code> . This will apply also in case of <code>moveAfterRead</code> option enabled and it will create the <code>destinationBucket</code> if it doesn't exist already.	false	boolean
overrideEndpoint (common)	Set the need for overriding the endpoint. This option needs to be used in combination with <code>uriEndpointOverride</code> option.	false	boolean
pojoRequest (common)	If we want to use a POJO request as body or not.	false	boolean
policy (common)	The policy for this queue to set in the <code>com.amazonaws.services.s3.AmazonS3#setBucketPolicy()</code> method.		String
proxyHost (common)	To define a proxy host when instantiating the SQS client.		String
proxyPort (common)	Specify a proxy port to be used inside the client definition.		Integer

Name	Description	Default	Type
proxyProtocol (common)	To define a proxy protocol when instantiating the S3 client. Enum values: • HTTP • HTTPS	HTTPS	Protocol
region (common)	The region in which S3 client needs to work. When using this parameter, the configuration will expect the lowercase name of the region (for example ap-east-1) You'll need to use the name Region.EU_WEST_1.id().		String
trustAllCertificates (common)	If we want to trust all certificates in case of overriding the endpoint.	false	boolean
uriEndpointOverride (common)	Set the overriding uri endpoint. This option needs to be used in combination with overrideEndpoint option.		String
useDefaultCredentialsProvider (common)	Set whether the S3 client should expect to load credentials through a default credentials provider or to expect static credentials to be passed in.	false	boolean
customerAlgorithm (common (advanced))	Define the customer algorithm to use in case CustomerKey is enabled.		String
customerKeyId (common (advanced))	Define the id of Customer key to use in case CustomerKey is enabled.		String
customerKeyMD5 (common (advanced))	Define the MD5 of Customer key to use in case CustomerKey is enabled.		String
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean

Name	Description	Default	Type
deleteAfterRead (consumer)	Delete objects from S3 after they have been retrieved. The delete is only performed if the Exchange is committed. If a rollback occurs, the object is not deleted. If this option is false, then the same objects will be retrieve over and over again on the polls. Therefore you need to use the Idempotent Consumer EIP in the route to filter out duplicates. You can filter using the <code>AWS2S3Constants#BUCKET_NAME</code> and <code>AWS2S3Constants#KEY</code> headers, or only the <code>AWS2S3Constants#KEY</code> header.	true	boolean
delimiter (consumer)	The delimiter which is used in the <code>com.amazonaws.services.s3.model.ListObjectsRequest</code> to only consume objects we are interested in.		String
destinationBucket (consumer)	Define the destination bucket where an object must be moved when <code>moveAfterRead</code> is set to true.		String
destinationBucketPrefix (consumer)	Define the destination bucket prefix to use when an object must be moved and <code>moveAfterRead</code> is set to true.		String
destinationBucketSuffix (consumer)	Define the destination bucket suffix to use when an object must be moved and <code>moveAfterRead</code> is set to true.		String
doneFileName (consumer)	If provided, Camel will only consume files if a done file exists.		String
fileName (consumer)	To get the object from the bucket with the given file name.		String
ignoreBody (consumer)	If it is true, the S3 Object Body will be ignored completely, if it is set to false the S3 Object will be put in the body. Setting this to true, will override any behavior defined by <code>includeBody</code> option.	false	boolean

Name	Description	Default	Type
includeBody (consumer)	If it is true, the S3Object exchange will be consumed and put into the body and closed. If false the S3Object stream will be put raw into the body and the headers will be set with the S3 object metadata. This option is strongly related to autocloseBody option. In case of setting includeBody to true because the S3Object stream will be consumed then it will also be closed, while in case of includeBody false then it will be up to the caller to close the S3Object stream. However setting autocloseBody to true when includeBody is false it will schedule to close the S3Object stream automatically on exchange completion.	true	boolean
includeFolders (consumer)	If it is true, the folders/directories will be consumed. If it is false, they will be ignored, and Exchanges will not be created for those.	true	boolean
maxConnections (consumer)	Set the maxConnections parameter in the S3 client configuration.	60	int
maxMessagesPer Poll (consumer)	Gets the maximum number of messages as a limit to poll at each polling. Gets the maximum number of messages as a limit to poll at each polling. The default value is 10. Use 0 or a negative number to set it as unlimited.	10	int
moveAfterRead (consumer)	Move objects from S3 bucket to a different bucket after they have been retrieved. To accomplish the operation the destinationBucket option must be set. The copy bucket operation is only performed if the Exchange is committed. If a rollback occurs, the object is not moved.	false	boolean
prefix (consumer)	The prefix which is used in the com.amazonaws.services.s3.model.ListObjectsRequest to only consume objects we are interested in.		String
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean

Name	Description	Default	Type
autocloseBody (consumer (advanced))	If this option is true and includeBody is false, then the <code>S3Object.close()</code> method will be called on exchange completion. This option is strongly related to includeBody option. In case of setting includeBody to false and autocloseBody to false, it will be up to the caller to close the <code>S3Object</code> stream. Setting autocloseBody to true, will close the <code>S3Object</code> stream automatically.	true	boolean
exceptionHandler (consumer (advanced))	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at <code>WARN</code> or <code>ERROR</code> level and ignored.		<code>ExceptionHandler</code>
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • <code>InOnly</code> • <code>InOut</code> • <code>InOptionalOut</code>		<code>ExchangePattern</code>
pollStrategy (consumer (advanced))	A pluggable <code>org.apache.camel.PollingConsumerPollingStrategy</code> allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an <code>Exchange</code> have been created and being routed in Camel.		<code>PollingConsumerPollStrategy</code>
batchMessageNumber (producer)	The number of messages composing a batch in streaming upload mode.	10	int
batchSize (producer)	The batch size (in bytes) in streaming upload mode.	100000	int
deleteAfterWrite (producer)	Delete file object after the S3 file has been uploaded.	false	boolean
keyName (producer)	Setting the key name for an element in the bucket through endpoint parameter.		String

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
multiPartUpload (producer)	If it is true, camel will upload the file with multi part format, the part size is decided by the option of partSize.	false	boolean
namingStrategy (producer)	The naming strategy to use in streaming upload mode. Enum values: ● progressive ● random	progressive	AWSS3NamingStrategyEnum
operation (producer)	The operation to do in case the user don't want to do only an upload. Enum values: ● copyObject ● listObjects ● deleteObject ● deleteBucket ● listBuckets ● getObject ● getObjectRange ● createDownloadLink		AWS2S3Operations
partSize (producer)	Setup the partSize which is used in multi part upload, the default size is 25M.	26214400	long

Name	Description	Default	Type
restartingPolicy (producer)	The restarting policy to use in streaming upload mode. Enum values: ● <code>override</code> ● <code>lastPart</code>	<code>override</code>	<code>AWSS3RestartingPolicyEnum</code>
storageClass (producer)	The storage class to set in the <code>com.amazonaws.services.s3.model.PutObjectRequest</code> request.		<code>String</code>
streamingUploadMode (producer)	When stream mode is true the upload to bucket will be done in streaming.	<code>false</code>	<code>boolean</code>
streamingUploadTimeout (producer)	While streaming upload mode is true, this option set the timeout to complete upload.		<code>long</code>
awsKMSKeyId (producer (advanced))	Define the id of KMS key to use in case KMS is enabled.		<code>String</code>
useAwsKMS (producer (advanced))	Define if KMS must be used or not.	<code>false</code>	<code>boolean</code>
useCustomerKey (producer (advanced))	Define if Customer Key must be used or not.	<code>false</code>	<code>boolean</code>
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the <code>backoffMultiplier</code> should kick-in.		<code>int</code>
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the <code>backoffMultiplier</code> should kick-in.		<code>int</code>
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then <code>backoffIdleThreshold</code> and/or <code>backoffErrorThreshold</code> must also be configured.		<code>int</code>
delay (scheduler)	Milliseconds before the next poll.	<code>500</code>	<code>long</code>

Name	Description	Default	Type
greedy (scheduler)	If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts.	1000	long
repeatCount (scheduler)	Specifies a maximum limit of number of fires. So if you set it to 1, the scheduler will only fire once. If you set it to 5, it will only fire five times. A value of zero or negative means fire forever.	0	long
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that. Enum values: ● TRACE ● DEBUG ● INFO ● WARN ● ERROR ● OFF	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz component. Use value spring or quartz for built in scheduler.	none	Object
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean

Name	Description	Default	Type
timeUnit (scheduler)	Time unit for initialDelay and delay options. Enum values: • NANOSECONDS • MICROSECONDS • MILLISECONDS • SECONDS • MINUTES • HOURS • DAYS	MILLISECONDS	TimeUnit
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.	true	boolean
accessKey (security)	Amazon AWS Access Key.		String
secretKey (security)	Amazon AWS Secret Key.		String

Required S3 component options

You have to provide the `amazonS3Client` in the Registry or your `accessKey` and `secretKey` to access the [Amazon's S3](#).

9.6. BATCH CONSUMER

This component implements the Batch Consumer.

This allows you for instance to know how many messages exists in this batch and for instance let the Aggregator aggregate this number of messages.

9.7. USAGE

For example in order to read file **hello.txt** from bucket **helloBucket**, use the following snippet:

```
from("aws2-s3://helloBucket?
accessKey=yourAccessKey&secretKey=yourSecretKey&prefix=hello.txt")
.to("file:/var/downloaded");
```

9.7.1. Message headers evaluated by the S3 producer

Header	Type	Description
CamelAwsS3BucketName	String	The bucket Name which this object will be stored or which will be used for the current operation
CamelAwsS3BucketDestinationName	String	The bucket Destination Name which will be used for the current operation
CamelAwsS3ContentLength	Long	The content length of this object.
CamelAwsS3ContentType	String	The content type of this object.
CamelAwsS3ContentControl	String	The content control of this object.
CamelAwsS3ContentDisposition	String	The content disposition of this object.
CamelAwsS3ContentEncoding	String	The content encoding of this object.
CamelAwsS3ContentMD5	String	The md5 checksum of this object.
CamelAwsS3DestinationKey	String	The Destination key which will be used for the current operation
CamelAwsS3Key	String	The key under which this object will be stored or which will be used for the current operation
CamelAwsS3LastModified	java.util.Date	The last modified timestamp of this object.
CamelAwsS3Operation	String	The operation to perform. Permitted values are copyObject, deleteObject, listBuckets, deleteBucket, listObjects
CamelAwsS3StorageClass	String	The storage class of this object.
CamelAwsS3CannedAcl	String	The canned acl that will be applied to the object. see software.amazon.awssdk.services.s3.model.ObjectCannedACL for allowed values.
CamelAwsS3Acl	software.amazon.awssdk.services.s3.model.BucketCannedACL	A well constructed Amazon S3 Access Control List object. see software.amazon.awssdk.services.s3.model.BucketCannedACL for more details

Header	Type	Description
CamelAwsS3ServerSideEncryption	String	Sets the server-side encryption algorithm when encrypting the object using AWS-managed keys. For example use AES256.
CamelAwsS3VersionId	String	The version Id of the object to be stored or returned from the current operation
CamelAwsS3Metadata	Map<String, String>	A map of metadata to be stored with the object in S3. More details about metadata .

9.7.2. Message headers set by the S3 producer

Header	Type	Description
CamelAwsS3ETag	String	The ETag value for the newly uploaded object.
CamelAwsS3VersionId	String	The optional version ID of the newly uploaded object.

9.7.3. Message headers set by the S3 consumer

Header	Type	Description
CamelAwsS3Key	String	The key under which this object is stored.
CamelAwsS3BucketName	String	The name of the bucket in which this object is contained.
CamelAwsS3ETag	String	The hex encoded 128-bit MD5 digest of the associated object according to RFC 1864. This data is used as an integrity check to verify that the data received by the caller is the same data that was sent by Amazon S3.
CamelAwsS3LastModified	Date	The value of the Last-Modified header, indicating the date and time at which Amazon S3 last recorded a modification to the associated object.
CamelAwsS3VersionId	String	The version ID of the associated Amazon S3 object if available. Version IDs are only assigned to objects when an object is uploaded to an Amazon S3 bucket that has object versioning enabled.

Header	Type	Description
CamelAwsS3ContentType	String	The Content-Type HTTP header, which indicates the type of content stored in the associated object. The value of this header is a standard MIME type.
CamelAwsS3ContentMD5	String	The base64 encoded 128-bit MD5 digest of the associated object (content - not including headers) according to RFC 1864. This data is used as a message integrity check to verify that the data received by Amazon S3 is the same data that the caller sent.
CamelAwsS3ContentLength	Long	The Content-Length HTTP header indicating the size of the associated object in bytes.
CamelAwsS3ContentEncoding	String	The optional Content-Encoding HTTP header specifying what content encodings have been applied to the object and what decoding mechanisms must be applied in order to obtain the media-type referenced by the Content-Type field.
CamelAwsS3ContentDisposition	String	The optional Content-Disposition HTTP header, which specifies presentational information such as the recommended filename for the object to be saved as.
CamelAwsS3ContentControl	String	The optional Cache-Control HTTP header which allows the user to specify caching behavior along the HTTP request/reply chain.
CamelAwsS3ServerSideEncryption	String	The server-side encryption algorithm when encrypting the object using AWS-managed keys.
CamelAwsS3Metadata	Map<String, String>	A map of metadata stored with the object in S3. More details about metadata .

9.7.4. S3 Producer operations

Camel-AWS2-S3 component provides the following operation on the producer side:

- copyObject
- deleteObject
- listBuckets
- deleteBucket
- listObjects

- getObject (this will return an S3Object instance)
- getObjectRange (this will return an S3Object instance)
- createDownloadLink

If you don't specify an operation explicitly the producer will do: - a single file upload - a multipart upload if multiPartUpload option is enabled.

9.7.5. Advanced AmazonS3 configuration

If your Camel Application is running behind a firewall or if you need to have more control over the **S3Client** instance configuration, you can create your own instance and refer to it in your Camel aws2-s3 component configuration:

```
from("aws2-s3://MyBucket?amazonS3Client=#client&delay=5000&maxMessagesPerPoll=5")
.to("mock:result");
```

9.7.6. Use KMS with the S3 component

To use AWS KMS to encrypt/decrypt data by using AWS infrastructure you can use the options introduced in 2.21.x like in the following example

```
from("file:tmp/test?fileName=test.txt")
.setHeader(S3Constants.KEY, constant("testFile"))
.to("aws2-s3://mybucket?amazonS3Client=#client&useAwsKMS=true&awsKMSKeyId=3f0637ad-296a-3dfe-a796-e60654fb128c");
```

In this way you'll ask to S3, to use the KMS key 3f0637ad-296a-3dfe-a796-e60654fb128c, to encrypt the file test.txt. When you'll ask to download this file, the decryption will be done directly before the download.

9.7.7. Static credentials vs Default Credential Provider

You have the possibility of avoiding the usage of explicit static credentials, by specifying the useDefaultCredentialsProvider option and set it to true.

- Java system properties - aws.accessKeyId and aws.secretKey
- Environment variables - AWS_ACCESS_KEY_ID and AWS_SECRET_ACCESS_KEY.
- Web Identity Token from AWS STS.
- The shared credentials and config files.
- Amazon ECS container credentials - loaded from the Amazon ECS if the environment variable AWS_CONTAINER_CREDENTIALS_RELATIVE_URI is set.
- Amazon EC2 Instance profile credentials.

For more information about this you can look at [AWS credentials documentation](#)

9.7.8. S3 Producer Operation examples

- Single Upload: This operation will upload a file to S3 based on the body content

```
from("direct:start").process(new Processor() {

    @Override
    public void process(Exchange exchange) throws Exception {
        exchange.getIn().setHeader(S3Constants.KEY, "camel.txt");
        exchange.getIn().setBody("Camel rocks!");
    }
})
.to("aws2-s3://mycamelbucket?amazonS3Client=#amazonS3Client")
.to("mock:result");
```

This operation will upload the file camel.txt with the content "Camel rocks!" in the mycamelbucket bucket

- Multipart Upload: This operation will perform a multipart upload of a file to S3 based on the body content

```
from("direct:start").process(new Processor() {

    @Override
    public void process(Exchange exchange) throws Exception {
        exchange.getIn().setHeader(AWS2S3Constants.KEY, "empty.txt");
        exchange.getIn().setBody(new File("src/empty.txt"));
    }
})
.to("aws2-s3://mycamelbucket?amazonS3Client=#amazonS3Client&multiPartUpload=true&autoCreateBucket=true&partSize=1048576'")
.to("mock:result");
```

This operation will perform a multipart upload of the file empty.txt with based on the content the file src/empty.txt in the mycamelbucket bucket

- CopyObject: this operation copy an object from one bucket to a different one

```
from("direct:start").process(new Processor() {

    @Override
    public void process(Exchange exchange) throws Exception {
        exchange.getIn().setHeader(S3Constants.BUCKET_DESTINATION_NAME,
"camelDestinationBucket");
        exchange.getIn().setHeader(S3Constants.KEY, "camelKey");
        exchange.getIn().setHeader(S3Constants.DESTINATION_KEY, "camelDestinationKey");
    }
})
.to("aws2-s3://mycamelbucket?amazonS3Client=#amazonS3Client&operation=copyObject")
.to("mock:result");
```

This operation will copy the object with the name expressed in the header camelDestinationKey to the camelDestinationBucket bucket, from the bucket mycamelbucket.

- DeleteObject: this operation deletes an object from a bucket

```

from("direct:start").process(new Processor() {

    @Override
    public void process(Exchange exchange) throws Exception {
        exchange.getIn().setHeader(S3Constants.KEY, "camelKey");
    }
})
.to("aws2-s3://mycamelbucket?amazonS3Client=#amazonS3Client&operation=deleteObject")
.to("mock:result");

```

This operation will delete the object camelKey from the bucket mycamelbucket.

- ListBuckets: this operation list the buckets for this account in this region

```

from("direct:start")
.to("aws2-s3://mycamelbucket?amazonS3Client=#amazonS3Client&operation=listBuckets")
.to("mock:result");

```

This operation will list the buckets for this account

- DeleteBucket: this operation delete the bucket specified as URI parameter or header

```

from("direct:start")
.to("aws2-s3://mycamelbucket?amazonS3Client=#amazonS3Client&operation=deleteBucket")
.to("mock:result");

```

This operation will delete the bucket mycamelbucket

- ListObjects: this operation list object in a specific bucket

```

from("direct:start")
.to("aws2-s3://mycamelbucket?amazonS3Client=#amazonS3Client&operation=listObjects")
.to("mock:result");

```

This operation will list the objects in the mycamelbucket bucket

- GetObject: this operation get a single object in a specific bucket

```

from("direct:start").process(new Processor() {

    @Override
    public void process(Exchange exchange) throws Exception {
        exchange.getIn().setHeader(S3Constants.KEY, "camelKey");
    }
})
.to("aws2-s3://mycamelbucket?amazonS3Client=#amazonS3Client&operation=getObject")
.to("mock:result");

```

This operation will return an S3Object instance related to the camelKey object in mycamelbucket bucket.

- GetObjectRange: this operation get a single object range in a specific bucket

```

from("direct:start").process(new Processor() {

```

```

@Override
public void process(Exchange exchange) throws Exception {
    exchange.getIn().setHeader(S3Constants.KEY, "camelKey");
    exchange.getIn().setHeader(S3Constants.RANGE_START, "0");
    exchange.getIn().setHeader(S3Constants.RANGE_END, "9");
}
})
.to("aws2-s3://mycamelbucket?amazonS3Client=#amazonS3Client&operation=getObjectRange")
.to("mock:result");

```

This operation will return an S3Object instance related to the camelKey object in mycamelbucket bucket, containing a the bytes from 0 to 9.

- CreateDownloadLink: this operation will return a download link through S3 Presigner

```

from("direct:start").process(new Processor() {

    @Override
    public void process(Exchange exchange) throws Exception {
        exchange.getIn().setHeader(S3Constants.KEY, "camelKey");
    }
})
.to("aws2-s3://mycamelbucket?
accessKey=xxx&secretKey=yyy&region=region&operation=createDownloadLink")
.to("mock:result");

```

This operation will return a download link url for the file camel-key in the bucket mycamelbucket and region region

9.8. STREAMING UPLOAD MODE

With the stream mode enabled users will be able to upload data to S3 without knowing ahead of time the dimension of the data, by leveraging multipart upload. The upload will be completed when: the batchSize has been completed or the batchSize has been reached. There are two possible naming strategy:

- progressive
With the progressive strategy each file will have the name composed by keyName option and a progressive counter, and eventually the file extension (if any)
- random.
With the random strategy a UUID will be added after keyName and eventually the file extension will appended.

As an example:

```

from(kafka("topic1").brokers("localhost:9092"))
    .log("Kafka Message is: ${body}")
    .to(aws2S3("camel-
bucket").streamingUploadMode(true).batchMessageNumber(25).namingStrategy(AWS2S3EndpointBu
ilderFactory.AWSS3NamingStrategyEnum.progressive).keyName("
{{kafkaTopic1}}/{{kafkaTopic1}}.txt"));

from(kafka("topic2").brokers("localhost:9092"))

```

```

        .log("Kafka Message is: ${body}")
        .to(aws2S3("camel-
bucket").streamingUploadMode(true).batchMessageNumber(25).namingStrategy(AWS2S3EndpointBu
ilderFactory.AWSS3NamingStrategyEnum.progressive).keyName("
{{kafkaTopic2}}/{{kafkaTopic2}}.txt"));

```

The default size for a batch is 1 Mb, but you can adjust it according to your requirements.

When you'll stop your producer route, the producer will take care of flushing the remaining buffered messaged and complete the upload.

In Streaming upload you'll be able restart the producer from the point where it left. It's important to note that this feature is critical only when using the progressive naming strategy.

By setting the restartingPolicy to lastPart, you will restart uploading files and contents from the last part number the producer left.

Example

1. Start the route with progressive naming strategy and keyname equals to camel.txt, with batchMessageNumber equals to 20, and restartingPolicy equals to lastPart - Send 70 messages.
2. Stop the route
3. On your S3 bucket you should now see 4 files: * camel.txt
 - camel-1.txt
 - camel-2.txt
 - camel-3.txt

The first three will have 20 messages, while the last one only 10.
4. Restart the route.
5. Send 25 messages.
6. Stop the route.
7. You'll now have 2 other files in your bucket: camel-5.txt and camel-6.txt, the first with 20 messages and second with 5 messages.
8. Go ahead

This won't be needed when using the random naming strategy.

On the opposite you can specify the override restartingPolicy. In that case you'll be able to override whatever you written before (for that particular keyName) on your bucket.

NOTE

In Streaming upload mode the only keyName option that will be taken into account is the endpoint option. Using the header will throw an NPE and this is done by design. Setting the header means potentially change the file name on each exchange and this is against the aim of the streaming upload producer. The keyName needs to be fixed and static. The selected naming strategy will do the rest of the work.

Another possibility is specifying a `streamingUploadTimeout` with `batchMessageNumber` and `batchSize` options. With this option the user will be able to complete the upload of a file after a certain time passed. In this way the upload completion will be passed on three tiers: the timeout, the number of messages and the batch size.

As an example:

```
from(kafka("topic1").brokers("localhost:9092"))
  .log("Kafka Message is: ${body}")
  .to(aws2S3("camel-
bucket").streamingUploadMode(true).batchMessageNumber(25).streamingUploadTimeout(10000).na
mingStrategy(AWS2S3EndpointBuilderFactory.AWSS3NamingStrategyEnum.progressive).keyName(
"{{kafkaTopic1}}/{{kafkaTopic1}}.txt"));
```

In this case the upload will be completed after 10 seconds.

9.9. BUCKET AUTOCREATION

With the option **autoCreateBucket** users are able to avoid the autocreation of an S3 Bucket in case it doesn't exist. The default for this option is **true**. If set to false any operation on a not-existent bucket in AWS won't be successful and an error will be returned.

9.10. MOVING STUFF BETWEEN A BUCKET AND ANOTHER BUCKET

Some users like to consume stuff from a bucket and move the content in a different one without using the `copyObject` feature of this component. If this is case for you, don't forget to remove the `bucketName` header from the incoming exchange of the consumer, otherwise the file will be always overwritten on the same original bucket.

9.11. MOVEAFTERREAD CONSUMER OPTION

In addition to `deleteAfterRead` it has been added another option, `moveAfterRead`. With this option enabled the consumed object will be moved to a target `destinationBucket` instead of being only deleted. This will require specifying the `destinationBucket` option. As example:

```
from("aws2-s3://mycamelbucket?
amazonS3Client=#amazonS3Client&moveAfterRead=true&destinationBucket=myothercamelbucket")
.to("mock:result");
```

In this case the objects consumed will be moved to `myothercamelbucket` bucket and deleted from the original one (because of `deleteAfterRead` set to true as default).

You have also the possibility of using a key prefix/suffix while moving the file to a different bucket. The options are `destinationBucketPrefix` and `destinationBucketSuffix`.

Taking the above example, you could do something like:

```
from("aws2-s3://mycamelbucket?
amazonS3Client=#amazonS3Client&moveAfterRead=true&destinationBucket=myothercamelbucket&de
stinationBucketPrefix=RAW(pre-)&destinationBucketSuffix=RAW(-suff)")
.to("mock:result");
```

In this case the objects consumed will be moved to myothercamelbucket bucket and deleted from the original one (because of deleteAfterRead set to true as default).

So if the file name is test, in the myothercamelbucket you should see a file called pre-test-suff.

9.12. USING CUSTOMER KEY AS ENCRYPTION

We introduced also the customer key support (an alternative of using KMS). The following code shows an example.

```
String key = UUID.randomUUID().toString();
byte[] secretKey = generateSecretKey();
String b64Key = Base64.getEncoder().encodeToString(secretKey);
String b64KeyMd5 = Md5Utils.md5AsBase64(secretKey);

String awsEndpoint = "aws2-s3://mycamel?
autoCreateBucket=false&useCustomerKey=true&customerKeyId=RAW(" + b64Key +
"&customerKeyMD5=RAW(" + b64KeyMd5 + "&customerAlgorithm=" + AES256.name());

from("direct:putObject")
    .setHeader(AWS2S3Constants.KEY, constant("test.txt"))
    .setBody(constant("Test"))
    .to(awsEndpoint);
```

9.13. USING A POJO AS BODY

Sometimes build an AWS Request can be complex, because of multiple options. We introduce the possibility to use a POJO as body. In AWS S3 there are multiple operations you can submit, as an example for List brokers request, you can do something like:

```
from("direct:aws2-s3")
    .setBody(ListObjectsRequest.builder().bucket(bucketName).build())
    .to("aws2-s3://test?
amazonS3Client=#amazonS3Client&operation=listObjects&pojoRequest=true")
```

In this way you'll pass the request directly without the need of passing headers and options specifically related to this operation.

9.14. CREATE S3 CLIENT AND ADD COMPONENT TO REGISTRY

Sometimes you would want to perform some advanced configuration using AWS2S3Configuration which also allows to set the S3 client. You can create and set the S3 client in the component configuration as shown in the following example

```
String awsBucketAccessKey = "your_access_key";
String awsBucketSecretKey = "your_secret_key";

S3Client s3Client =
S3Client.builder().credentialsProvider(StaticCredentialsProvider.create(AwsBasicCredentials.create(aws
BucketAccessKey, awsBucketSecretKey)))
    .region(Region.US_EAST_1).build();

AWS2S3Configuration configuration = new AWS2S3Configuration();
```

```
configuration.setAmazonS3Client(s3Client);
configuration.setAutoDiscoverClient(true);
configuration.setBucketName("s3bucket2020");
configuration.setRegion("us-east-1");
```

Now you can configure the S3 component (using the configuration object created above) and add it to the registry in the configure method before initialization of routes.

```
AWS2S3Component s3Component = new AWS2S3Component(getContext());
s3Component.setConfiguration(configuration);
s3Component.setLazyStartProducer(true);
camelContext.addComponent("aws2-s3", s3Component);
```

Now your component will be used for all the operations implemented in camel routes.

9.15. DEPENDENCIES

Maven users will need to add the following dependency to their **pom.xml**.

pom.xml

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-aws2-s3</artifactId>
  <version>${camel-version}</version>
</dependency>
```

where **{camel-version}** must be replaced by the actual version of Camel.

9.16. SPRING BOOT AUTO-CONFIGURATION

The component supports 51 options, which are listed below.

Name	Description	Default	Type
camel.component.aws2-s3.access-key	Amazon AWS Access Key.		String
camel.component.aws2-s3.amazon-s3-client	Reference to a <code>com.amazonaws.services.s3.AmazonS3</code> in the registry. The option is a <code>software.amazon.awssdk.services.s3.S3Client</code> type.		S3Client
camel.component.aws2-s3.amazon-s3-presigner	An S3 Presigner for Request, used mainly in <code>createDownloadLink</code> operation. The option is a <code>software.amazon.awssdk.services.s3.presigner.S3Presigner</code> type.		S3Presigner

Name	Description	Default	Type
camel.component.aws2-s3.auto-create-bucket	Setting the autocreation of the S3 bucket bucketName. This will apply also in case of moveAfterRead option enabled and it will create the destinationBucket if it doesn't exist already.	false	Boolean
camel.component.aws2-s3.autoclose-body	If this option is true and includeBody is false, then the S3Object.close() method will be called on exchange completion. This option is strongly related to includeBody option. In case of setting includeBody to false and autocloseBody to false, it will be up to the caller to close the S3Object stream. Setting autocloseBody to true, will close the S3Object stream automatically.	true	Boolean
camel.component.aws2-s3.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.aws2-s3.aws-kms-key-id	Define the id of KMS key to use in case KMS is enabled.		String
camel.component.aws2-s3.batch-message-number	The number of messages composing a batch in streaming upload mode.	10	Integer
camel.component.aws2-s3.batch-size	The batch size (in bytes) in streaming upload mode.	1000000	Integer
camel.component.aws2-s3.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean

Name	Description	Default	Type
<code>camel.component.aws2-s3.configuration</code>	The component configuration. The option is a <code>org.apache.camel.component.aws2.s3.AWS2S3Configuration</code> type.		<code>AWS2S3Configuration</code>
<code>camel.component.aws2-s3.customer-algorithm</code>	Define the customer algorithm to use in case <code>CustomerKey</code> is enabled.		String
<code>camel.component.aws2-s3.customer-key-id</code>	Define the id of Customer key to use in case <code>CustomerKey</code> is enabled.		String
<code>camel.component.aws2-s3.customer-key-md5</code>	Define the MD5 of Customer key to use in case <code>CustomerKey</code> is enabled.		String
<code>camel.component.aws2-s3.delete-after-read</code>	Delete objects from S3 after they have been retrieved. The delete is only performed if the Exchange is committed. If a rollback occurs, the object is not deleted. If this option is false, then the same objects will be retrieve over and over again on the polls. Therefore you need to use the Idempotent Consumer EIP in the route to filter out duplicates. You can filter using the <code>AWS2S3Constants#BUCKET_NAME</code> and <code>AWS2S3Constants#KEY</code> headers, or only the <code>AWS2S3Constants#KEY</code> header.	true	Boolean
<code>camel.component.aws2-s3.delete-after-write</code>	Delete file object after the S3 file has been uploaded.	false	Boolean
<code>camel.component.aws2-s3.delimiter</code>	The delimiter which is used in the <code>com.amazonaws.services.s3.model.ListObjectsRequest</code> to only consume objects we are interested in.		String
<code>camel.component.aws2-s3.destination-bucket</code>	Define the destination bucket where an object must be moved when <code>moveAfterRead</code> is set to true.		String
<code>camel.component.aws2-s3.destination-bucket-prefix</code>	Define the destination bucket prefix to use when an object must be moved and <code>moveAfterRead</code> is set to true.		String

Name	Description	Default	Type
camel.component.aws2-s3.destination-bucket-suffix	Define the destination bucket suffix to use when an object must be moved and moveAfterRead is set to true.		String
camel.component.aws2-s3.done-file-name	If provided, Camel will only consume files if a done file exists.		String
camel.component.aws2-s3.enabled	Whether to enable auto configuration of the aws2-s3 component. This is enabled by default.		Boolean
camel.component.aws2-s3.file-name	To get the object from the bucket with the given file name.		String
camel.component.aws2-s3.ignore-body	If it is true, the S3 Object Body will be ignored completely, if it is set to false the S3 Object will be put in the body. Setting this to true, will override any behavior defined by includeBody option.	false	Boolean
camel.component.aws2-s3.include-body	If it is true, the S3Object exchange will be consumed and put into the body and closed. If false the S3Object stream will be put raw into the body and the headers will be set with the S3 object metadata. This option is strongly related to autocloseBody option. In case of setting includeBody to true because the S3Object stream will be consumed then it will also be closed, while in case of includeBody false then it will be up to the caller to close the S3Object stream. However setting autocloseBody to true when includeBody is false it will schedule to close the S3Object stream automatically on exchange completion.	true	Boolean
camel.component.aws2-s3.include-folders	If it is true, the folders/directories will be consumed. If it is false, they will be ignored, and Exchanges will not be created for those.	true	Boolean
camel.component.aws2-s3.key-name	Setting the key name for an element in the bucket through endpoint parameter.		String

Name	Description	Default	Type
camel.component.aws2-s3.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.aws2-s3.move-after-read	Move objects from S3 bucket to a different bucket after they have been retrieved. To accomplish the operation the destinationBucket option must be set. The copy bucket operation is only performed if the Exchange is committed. If a rollback occurs, the object is not moved.	false	Boolean
camel.component.aws2-s3.multi-part-upload	If it is true, camel will upload the file with multi part format, the part size is decided by the option of partSize.	false	Boolean
camel.component.aws2-s3.naming-strategy	The naming strategy to use in streaming upload mode.		AWSS3NamingStrategyEnum
camel.component.aws2-s3.operation	The operation to do in case the user don't want to do only an upload.		AWS2S3Operations
camel.component.aws2-s3.override-endpoint	Set the need for overriding the endpoint. This option needs to be used in combination with uriEndpointOverride option.	false	Boolean
camel.component.aws2-s3.part-size	Setup the partSize which is used in multi part upload, the default size is 25M.	26214400	Long
camel.component.aws2-s3.pojo-request	If we want to use a POJO request as body or not.	false	Boolean
camel.component.aws2-s3.policy	The policy for this queue to set in the com.amazonaws.services.s3.AmazonS3#setBucketPolicy() method.		String

Name	Description	Default	Type
<code>camel.component.aws2-s3.prefix</code>	The prefix which is used in the <code>com.amazonaws.services.s3.model.ListObjectsRequest</code> to only consume objects we are interested in.		String
<code>camel.component.aws2-s3.proxy-host</code>	To define a proxy host when instantiating the SQS client.		String
<code>camel.component.aws2-s3.proxy-port</code>	Specify a proxy port to be used inside the client definition.		Integer
<code>camel.component.aws2-s3.proxy-protocol</code>	To define a proxy protocol when instantiating the S3 client.		Protocol
<code>camel.component.aws2-s3.region</code>	The region in which S3 client needs to work. When using this parameter, the configuration will expect the lowercase name of the region (for example <code>ap-east-1</code>) You'll need to use the name <code>Region.EU_WEST_1.id()</code> .		String
<code>camel.component.aws2-s3.restarting-policy</code>	The restarting policy to use in streaming upload mode.		<code>AWSS3RestartingPolicyEnum</code>
<code>camel.component.aws2-s3.secret-key</code>	Amazon AWS Secret Key.		String
<code>camel.component.aws2-s3.storage-class</code>	The storage class to set in the <code>com.amazonaws.services.s3.model.PutObjectRequest</code> request.		String
<code>camel.component.aws2-s3.streaming-upload-mode</code>	When stream mode is true the upload to bucket will be done in streaming.	false	Boolean
<code>camel.component.aws2-s3.streaming-upload-timeout</code>	While streaming upload mode is true, this option set the timeout to complete upload.		Long
<code>camel.component.aws2-s3.trust-all-certificates</code>	If we want to trust all certificates in case of overriding the endpoint.	false	Boolean

Name	Description	Default	Type
<code>camel.component.aws2-s3.uri-endpoint-override</code>	Set the overriding uri endpoint. This option needs to be used in combination with <code>overrideEndpoint</code> option.		String
<code>camel.component.aws2-s3.use-aws-k-m-s</code>	Define if KMS must be used or not.	false	Boolean
<code>camel.component.aws2-s3.use-customer-key</code>	Define if Customer Key must be used or not.	false	Boolean
<code>camel.component.aws2-s3.use-default-credentials-provider</code>	Set whether the S3 client should expect to load credentials through a default credentials provider or to expect static credentials to be passed in.	false	Boolean

CHAPTER 10. AWS SIMPLE NOTIFICATION SYSTEM (SNS)

Only producer is supported

The AWS2 SNS component allows messages to be sent to an [Amazon Simple Notification](#) Topic. The implementation of the Amazon API is provided by the [AWS SDK](#).

Prerequisites

You must have a valid Amazon Web Services developer account, and be signed up to use Amazon SNS. More information is available at [Amazon SNS](#).

10.1. DEPENDENCIES

When using **aws2-sns** with Red Hat build of Camel Spring Boot, add the following Maven dependency to your **pom.xml** to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-aws2-sns-starter</artifactId>
</dependency>
```

10.2. URI FORMAT

```
aws2-sns://topicNameOrArn[?options]
```

The topic will be created if they don't already exists. You can append query options to the URI in the following format,

```
?options=value&option2=value&...
```

10.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

10.3.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).

- directly in the Java code.

10.3.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

10.4. COMPONENT OPTIONS

The AWS Simple Notification System (SNS) component supports 24 options, which are listed below.

Name	Description	Default	Type
amazonSNSClient (producer)	Autowired To use the AmazonSNS as the client.		SnsClient
autoCreateTopic (producer)	Setting the autocreation of the topic.	false	boolean
configuration (producer)	Component configuration.		Sns2Configuration
kmsMasterKeyId (producer)	The ID of an AWS-managed customer master key (CMK) for Amazon SNS or a custom CMK.		String

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
messageDeduplicationIdStrategy (producer)	Only for FIFO Topic. Strategy for setting the messageDeduplicationId on the message. Can be one of the following options: useExchangeId, useContentBasedDeduplication. For the useContentBasedDeduplication option, no messageDeduplicationId will be set on the message. Enum values: ● useExchangeId ● useContentBasedDeduplication	useExchangeId	String
messageGroupIdStrategy (producer)	Only for FIFO Topic. Strategy for setting the messageGroupId on the message. Can be one of the following options: useConstant, useExchangeId, usePropertyValue. For the usePropertyValue option, the value of property CamelAwsMessageGroupId will be used. Enum values: ● useConstant ● useExchangeId ● usePropertyValue		String
messageStructure (producer)	The message structure to use such as json.		String
overrideEndpoint (producer)	Set the need for overriding the endpoint. This option needs to be used in combination with uriEndpointOverride option.	false	boolean
policy (producer)	The policy for this topic. Is loaded by default from classpath, but you can prefix with classpath:, file:, or http: to load the resource from different systems.		String

Name	Description	Default	Type
proxyHost (producer)	To define a proxy host when instantiating the SNS client.		String
proxyPort (producer)	To define a proxy port when instantiating the SNS client.		Integer
proxyProtocol (producer)	To define a proxy protocol when instantiating the SNS client. Enum values: • HTTP • HTTPS	HTTPS	Protocol
queueUrl (producer)	The queueUrl to subscribe to.		String
region (producer)	The region in which SNS client needs to work. When using this parameter, the configuration will expect the lowercase name of the region (for example ap-east-1) You'll need to use the name Region.EU_WEST_1.id().		String
serverSideEncryptionEnabled (producer)	Define if Server Side Encryption is enabled or not on the topic.	false	boolean
subject (producer)	The subject which is used if the message header 'CamelAwsSnsSubject' is not present.		String
subscribeSNSstoSQS (producer)	Define if the subscription between SNS Topic and SQS must be done or not.	false	boolean
trustAllCertificates (producer)	If we want to trust all certificates in case of overriding the endpoint.	false	boolean
uriEndpointOverride (producer)	Set the overriding uri endpoint. This option needs to be used in combination with overrideEndpoint option.		String
useDefaultCredentialsProvider (producer)	Set whether the SNS client should expect to load credentials on an AWS infra instance or to expect static credentials to be passed in.	false	boolean

Name	Description	Default	Type
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
accessKey (security)	Amazon AWS Access Key.		String
secretKey (security)	Amazon AWS Secret Key.		String

10.5. ENDPOINT OPTIONS

The AWS Simple Notification System (SNS) endpoint is configured using URI syntax:

```
aws2-sns:topicNameOrArn
```

with the following path and query parameters:

10.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
topicNameOrArn (producer)	Required Topic name or ARN.		String

10.5.2. Query Parameters (23 parameters)

Name	Description	Default	Type
amazonSNSClient (producer)	Autowired To use the AmazonSNS as the client.		SnsClient
autoCreateTopic (producer)	Setting the autocreation of the topic.	false	boolean
headerFilterStrategy (producer)	To use a custom HeaderFilterStrategy to map headers to/from Camel.		HeaderFilterStrategy

Name	Description	Default	Type
kmsMasterKeyId (producer)	The ID of an AWS-managed customer master key (CMK) for Amazon SNS or a custom CMK.		String
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
messageDeduplicationIdStrategy (producer)	Only for FIFO Topic. Strategy for setting the messageDeduplicationId on the message. Can be one of the following options: useExchangedId, useContentBasedDeduplication. For the useContentBasedDeduplication option, no messageDeduplicationId will be set on the message. Enum values: ● useExchangedId ● useContentBasedDeduplication	useExchangedId	String
messageGroupIdStrategy (producer)	Only for FIFO Topic. Strategy for setting the messageGroupId on the message. Can be one of the following options: useConstant, useExchangedId, usePropertyValue. For the usePropertyValue option, the value of property CamelAwsMessageGroupId will be used. Enum values: ● useConstant ● useExchangedId ● usePropertyValue		String
messageStructure (producer)	The message structure to use such as json.		String
overrideEndpoint (producer)	Set the need for overriding the endpoint. This option needs to be used in combination with uriEndpointOverride option.	false	boolean

Name	Description	Default	Type
policy (producer)	The policy for this topic. Is loaded by default from classpath, but you can prefix with classpath:, file:, or http: to load the resource from different systems.		String
proxyHost (producer)	To define a proxy host when instantiating the SNS client.		String
proxyPort (producer)	To define a proxy port when instantiating the SNS client.		Integer
proxyProtocol (producer)	To define a proxy protocol when instantiating the SNS client. Enum values: • HTTP • HTTPS	HTTPS	Protocol
queueUrl (producer)	The queueUrl to subscribe to.		String
region (producer)	The region in which SNS client needs to work. When using this parameter, the configuration will expect the lowercase name of the region (for example ap-east-1) You'll need to use the name Region.EU_WEST_1.id().		String
serverSideEncryptionEnabled (producer)	Define if Server Side Encryption is enabled or not on the topic.	false	boolean
subject (producer)	The subject which is used if the message header 'CamelAwsSnsSubject' is not present.		String
subscribeSNStoSQS (producer)	Define if the subscription between SNS Topic and SQS must be done or not.	false	boolean
trustAllCertificates (producer)	If we want to trust all certificates in case of overriding the endpoint.	false	boolean
uriEndpointOverride (producer)	Set the overriding uri endpoint. This option needs to be used in combination with overrideEndpoint option.		String
useDefaultCredentialsProvider (producer)	Set whether the SNS client should expect to load credentials on an AWS infra instance or to expect static credentials to be passed in.	false	boolean

Name	Description	Default	Type
accessKey (security)	Amazon AWS Access Key.		String
secretKey (security)	Amazon AWS Secret Key.		String

Required SNS component options

You have to provide the `amazonSNSClient` in the Registry or your `accessKey` and `secretKey` to access the [Amazon's SNS](#).

10.6. USAGE

10.6.1. Static credentials vs Default Credential Provider

You have the possibility of avoiding the usage of explicit static credentials, by specifying the `useDefaultCredentialsProvider` option and set it to `true`.

- Java system properties - `aws.accessKeyId` and `aws.secretKey`
- Environment variables - `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`.
- Web Identity Token from AWS STS.
- The shared credentials and config files.
- Amazon ECS container credentials - loaded from the Amazon ECS if the environment variable `AWS_CONTAINER_CREDENTIALS_RELATIVE_URI` is set.
- Amazon EC2 Instance profile credentials.

For more information about this you can look at [AWS credentials documentation](#).

10.6.2. Message headers evaluated by the SNS producer

Header	Type	Description
CamelAwsSnsSubject	String	The Amazon SNS message subject. If not set, the subject from the SnsConfiguration is used.

10.6.3. Message headers set by the SNS producer

Header	Type	Description
CamelAwsSnsMessageId	String	The Amazon SNS message ID.

10.6.4. Advanced AmazonSNS configuration

If you need more control over the **SnsClient** instance configuration you can create your own instance and refer to it from the URI:

```
from("direct:start")
.to("aws2-sns://MyTopic?amazonSNSClient=#client");
```

The **#client** refers to a **AmazonSNS** in the Registry.

10.6.5. Create a subscription between an AWS SNS Topic and an AWS SQS Queue

You can create a subscription of an SQS Queue to an SNS Topic in this way:

```
from("direct:start")
.to("aws2-sns://test-camel-sns1?
amazonSNSClient=#amazonSNSClient&subscribeSNStoSQS=true&queueUrl=https://sqs.eu-central-
1.amazonaws.com/780410022472/test-camel");
```

The **#amazonSNSClient** refers to a **SnsClient** in the Registry. By specifying **subscribeSNStoSQS** to true and a **queueUrl** of an existing SQS Queue, you'll be able to subscribe your SQS Queue to your SNS Topic.

At this point you can consume messages coming from SNS Topic through your SQS Queue

```
from("aws2-sqs://test-camel?
amazonSQSClient=#amazonSQSClient&delay=50&maxMessagesPerPoll=5")
.to(...);
```

10.7. TOPIC AUTOCREATION

With the option **autoCreateTopic** users are able to avoid the autocreation of an SNS Topic in case it doesn't exist. The default for this option is **true**. If set to false any operation on a not-existent topic in AWS won't be successful and an error will be returned.

10.8. SNS FIFO

SNS FIFO are supported. While creating the SQS queue you will subscribe to the SNS topic there is an important point to remember, you'll need to make possible for the SNS Topic to send message to the SQS Queue.

Example

Suppose you created an SNS FIFO Topic called **Order.fifo** and an SQS Queue called **QueueSub.fifo**.

In the access Policy of the **QueueSub.fifo** you should submit something like this:

```
{
  "Version": "2008-10-17",
  "Id": "__default_policy_ID",
  "Statement": [
    {
      "Sid": "__owner_statement",
```

```

    "Effect": "Allow",
    "Principal": {
      "AWS": "arn:aws:iam::780560123482:root"
    },
    "Action": "SQS:*",
    "Resource": "arn:aws:sqs:eu-west-1:780560123482:QueueSub.fifo"
  },
  {
    "Effect": "Allow",
    "Principal": {
      "Service": "sns.amazonaws.com"
    },
    "Action": "SQS:SendMessage",
    "Resource": "arn:aws:sqs:eu-west-1:780560123482:QueueSub.fifo",
    "Condition": {
      "ArnLike": {
        "aws:SourceArn": "arn:aws:sns:eu-west-1:780410022472:Order.fifo"
      }
    }
  }
]
}

```

This is a critical step to make the subscription work correctly.

10.8.1. SNS Fifo Topic Message group Id Strategy and message Deduplication Id Strategy

When sending something to the FIFO topic you'll need to always set up a message group Id strategy.

If the content-based message deduplication has been enabled on the SNS Fifo topic, there won't be the need of setting a message deduplication id strategy, otherwise you'll have to set it.

10.9. EXAMPLES

10.9.1. Producer Examples

Sending to a topic

```

from("direct:start")
.to("aws2-sns://camel-topic?subject=The+subject+message&autoCreateTopic=true");

```

10.10. DEPENDENCIES

Maven users will need to add the following dependency to their pom.xml.

pom.xml

```

<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-aws2-sns</artifactId>
  <version>${camel-version}</version>
</dependency>

```

where **{camel-version}** must be replaced by the actual version of Camel.

10.11. SPRING BOOT AUTO-CONFIGURATION

The component supports 25 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.aws2-sns.access-key</code>	Amazon AWS Access Key.		String
<code>camel.component.aws2-sns.amazon-sns-client</code>	To use the AmazonSNS as the client. The option is a <code>software.amazon.awssdk.services.sns.SnsClient</code> type.		SnsClient
<code>camel.component.aws2-sns.auto-create-topic</code>	Setting the autocreation of the topic.	false	Boolean
<code>camel.component.aws2-sns.autowired-enabled</code>	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
<code>camel.component.aws2-sns.configuration</code>	Component configuration. The option is a <code>org.apache.camel.component.aws2.sns.Sns2Configuration</code> type.		Sns2Configuration
<code>camel.component.aws2-sns.enabled</code>	Whether to enable auto configuration of the aws2-sns component. This is enabled by default.		Boolean
<code>camel.component.aws2-sns.kms-master-key-id</code>	The ID of an AWS-managed customer master key (CMK) for Amazon SNS or a custom CMK.		String

Name	Description	Default	Type
camel.component .aws2-sns.lazy- start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component .aws2- sns.message- deduplication-id- strategy	Only for FIFO Topic. Strategy for setting the messageDeduplicationId on the message. Can be one of the following options: useExchangeId, useContentBasedDeduplication. For the useContentBasedDeduplication option, no messageDeduplicationId will be set on the message.	useExchangeId	String
camel.component .aws2- sns.message- group-id- strategy	Only for FIFO Topic. Strategy for setting the messageGroupId on the message. Can be one of the following options: useConstant, useExchangeId, usePropertyValue. For the usePropertyValue option, the value of property CamelAwsMessageGroupId will be used.		String
camel.component .aws2- sns.message- structure	The message structure to use such as json.		String
camel.component .aws2- sns.override- endpoint	Set the need for overriding the endpoint. This option needs to be used in combination with uriEndpointOverride option.	false	Boolean
camel.component .aws2-sns.policy	The policy for this topic. Is loaded by default from classpath, but you can prefix with classpath:, file:, or http: to load the resource from different systems.		String
camel.component .aws2-sns.proxy- host	To define a proxy host when instantiating the SNS client.		String
camel.component .aws2-sns.proxy- port	To define a proxy port when instantiating the SNS client.		Integer

Name	Description	Default	Type
<code>camel.component.aws2-sns.proxy-protocol</code>	To define a proxy protocol when instantiating the SNS client.		Protocol
<code>camel.component.aws2-sns.queue-url</code>	The queueUrl to subscribe to.		String
<code>camel.component.aws2-sns.region</code>	The region in which SNS client needs to work. When using this parameter, the configuration will expect the lowercase name of the region (for example ap-east-1) You'll need to use the name <code>Region.EU_WEST_1.id()</code> .		String
<code>camel.component.aws2-sns.secret-key</code>	Amazon AWS Secret Key.		String
<code>camel.component.aws2-sns.server-side-encryption-enabled</code>	Define if Server Side Encryption is enabled or not on the topic.	false	Boolean
<code>camel.component.aws2-sns.subject</code>	The subject which is used if the message header 'CamelAwsSnsSubject' is not present.		String
<code>camel.component.aws2-sns.subscribe-s-n-sto-s-q-s</code>	Define if the subscription between SNS Topic and SQS must be done or not.	false	Boolean
<code>camel.component.aws2-sns.trust-all-certificates</code>	If we want to trust all certificates in case of overriding the endpoint.	false	Boolean
<code>camel.component.aws2-sns.uri-endpoint-override</code>	Set the overriding uri endpoint. This option needs to be used in combination with <code>overrideEndpoint</code> option.		String
<code>camel.component.aws2-sns.use-default-credentials-provider</code>	Set whether the SNS client should expect to load credentials on an AWS infra instance or to expect static credentials to be passed in.	false	Boolean

CHAPTER 11. AWS SIMPLE QUEUE SERVICE (SQS)

Both producer and consumer are supported

The AWS2 SQS component supports sending and receiving messages to [Amazon's SQS service](#).

Prerequisites

You must have a valid Amazon Web Services developer account, and be signed up to use Amazon SQS. More information is available at [Amazon SQS](#).

11.1. DEPENDENCIES

When using aws2-sqs with Red Hat build of Camel Spring Boot, add the following Maven dependency to your **pom.xml** to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-aws2-sqs-starter</artifactId>
</dependency>
```

11.2. URI FORMAT

```
aws2-sqs://queueNameOrArn[?options]
```

The queue will be created if they don't already exists. You can append query options to the URI in the following format,

?options=value&option2=value&...

11.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

11.3.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).

- directly in the Java code.

11.3.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

11.4. COMPONENT OPTIONS

The AWS Simple Queue Service (SQS) component supports 43 options, which are listed below.

Name	Description	Default	Type
amazonAWSHost (common)	The hostname of the Amazon AWS cloud.	amazonsqs.com	String
amazonSQSClient (common)	Autowired To use the AmazonSQS as client.		SqsClient
autoCreateQueue (common)	Setting the autocreation of the queue.	false	boolean
configuration (common)	The AWS SQS default configuration.		Sqs2Configuration
overrideEndpoint (common)	Set the need for overriding the endpoint. This option needs to be used in combination with <code>uriEndpointOverride</code> option.	false	boolean
protocol (common)	The underlying protocol used to communicate with SQS.	https	String

Name	Description	Default	Type
proxyProtocol (common)	To define a proxy protocol when instantiating the SQS client. Enum values: • HTTP • HTTPS	HTTPS	Protocol
queueOwnerAWSAccountId (common)	Specify the queue owner aws account id when you need to connect the queue with different account owner.		String
region (common)	The region in which SQS client needs to work. When using this parameter, the configuration will expect the lowercase name of the region (for example ap-east-1) You'll need to use the name Region.EU_WEST_1.id().		String
trustAllCertificates (common)	If we want to trust all certificates in case of overriding the endpoint.	false	boolean
uriEndpointOverride (common)	Set the overriding uri endpoint. This option needs to be used in combination with overrideEndpoint option.		String
useDefaultCredentialsProvider (common)	Set whether the SQS client should expect to load credentials on an AWS infra instance or to expect static credentials to be passed in.	false	boolean
attributeNames (consumer)	A list of attribute names to receive when consuming. Multiple names can be separated by comma.		String
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
concurrentConsumers (consumer)	Allows you to use multiple threads to poll the sqs queue to increase throughput.	1	int
defaultVisibilityTimeout (consumer)	The default visibility timeout (in seconds).		Integer

Name	Description	Default	Type
deleteAfterRead (consumer)	Delete message from SQS after it has been read.	true	boolean
deleteIfFiltered (consumer)	Whether or not to send the DeleteMessage to the SQS queue if the exchange has property with key <code>Sqs2Constants#SQS_DELETE_FILTERED</code> (CamelAwsSqsDeleteFiltered) set to true.	true	boolean
extendMessageVisibility (consumer)	If enabled then a scheduled background task will keep extending the message visibility on SQS. This is needed if it takes a long time to process the message. If set to true <code>defaultVisibilityTimeout</code> must be set.	false	boolean
kmsDataKeyReusePeriodSeconds (consumer)	The length of time, in seconds, for which Amazon SQS can reuse a data key to encrypt or decrypt messages before calling AWS KMS again. An integer representing seconds, between 60 seconds (1 minute) and 86,400 seconds (24 hours). Default: 300 (5 minutes).		Integer
kmsMasterKeyId (consumer)	The ID of an AWS-managed customer master key (CMK) for Amazon SQS or a custom CMK.		String
messageAttributeNames (consumer)	A list of message attribute names to receive when consuming. Multiple names can be separated by comma.		String
serverSideEncryptionEnabled (consumer)	Define if Server Side Encryption is enabled or not on the queue.	false	boolean
visibilityTimeout (consumer)	The duration (in seconds) that the received messages are hidden from subsequent retrieve requests after being retrieved by a <code>ReceiveMessage</code> request to set in the <code>com.amazonaws.services.sqs.model.SetQueueAttributesRequest</code> . This only make sense if its different from <code>defaultVisibilityTimeout</code> . It changes the queue visibility timeout attribute permanently.		Integer
waitTimeSeconds (consumer)	Duration in seconds (0 to 20) that the <code>ReceiveMessage</code> action call will wait until a message is in the queue to include in the response.		Integer
batchSeparator (producer)	Set the separator when passing a String to send batch message operation.	,	String

Name	Description	Default	Type
delaySeconds (producer)	Delay sending messages for a number of seconds.		Integer
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
messageDeduplicationIdStrategy (producer)	Only for FIFO queues. Strategy for setting the messageDeduplicationId on the message. Can be one of the following options: useExchangedId, useContentBasedDeduplication. For the useContentBasedDeduplication option, no messageDeduplicationId will be set on the message. Enum values: ● useExchangedId ● useContentBasedDeduplication	useExchangedId	String
messageGroupIdStrategy (producer)	Only for FIFO queues. Strategy for setting the messageGroupId on the message. Can be one of the following options: useConstant, useExchangedId, usePropertyValue. For the usePropertyValue option, the value of property CamelAwsMessageGroupId will be used. Enum values: ● useConstant ● useExchangedId ● usePropertyValue		String

Name	Description	Default	Type
operation (producer)	The operation to do in case the user don't want to send only a message. Enum values: ● <code>sendBatchMessage</code> ● <code>deleteMessage</code> ● <code>listQueues</code> ● <code>purgeQueue</code> ● <code>deleteQueue</code>		<code>Sqs2Operations</code>
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	<code>true</code>	<code>boolean</code>
delayQueue (advanced)	Define if you want to apply <code>delaySeconds</code> option to the queue or on single messages.	<code>false</code>	<code>boolean</code>
queueUrl (advanced)	To define the <code>queueUrl</code> explicitly. All other parameters, which would influence the <code>queueUrl</code> , are ignored. This parameter is intended to be used, to connect to a mock implementation of SQS, for testing purposes.		<code>String</code>
proxyHost (proxy)	To define a proxy host when instantiating the SQS client.		<code>String</code>
proxyPort (proxy)	To define a proxy port when instantiating the SQS client.		<code>Integer</code>
maximumMessageSize (queue)	The <code>maximumMessageSize</code> (in bytes) an SQS message can contain for this queue.		<code>Integer</code>
messageRetentionPeriod (queue)	The <code>messageRetentionPeriod</code> (in seconds) a message will be retained by SQS for this queue.		<code>Integer</code>
policy (queue)	The policy for this queue. It can be loaded by default from classpath, but you can prefix with <code>classpath:</code> , <code>file:</code> , or <code>http:</code> to load the resource from different systems.		<code>String</code>

Name	Description	Default	Type
receiveMessageWaitTimeSeconds (queue)	If you do not specify WaitTimeSeconds in the request, the queue attribute ReceiveMessageWaitTimeSeconds is used to determine how long to wait.		Integer
redrivePolicy (queue)	Specify the policy that send message to DeadLetter queue. See detail at Amazon docs.		String
accessKey (security)	Amazon AWS Access Key.		String
secretKey (security)	Amazon AWS Secret Key.		String

11.5. ENDPOINT OPTIONS

The AWS Simple Queue Service (SQS) endpoint is configured using URI syntax:

```
aws2-sqs:queueNameOrArn
```

with the following path and query parameters:

11.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
queueNameOrArn (common)	Required Queue name or ARN.		String

11.5.2. Query Parameters (61 parameters)

Name	Description	Default	Type
amazonAWSHost (common)	The hostname of the Amazon AWS cloud.	amazonaws.com	String
amazonSQSClient (common)	Autowired To use the AmazonSQS as client.		SqsClient
autoCreateQueue (common)	Setting the autocreation of the queue.	false	boolean

Name	Description	Default	Type
headerFilterStrategy (common)	To use a custom HeaderFilterStrategy to map headers to/from Camel.		HeaderFilterStrategy
overrideEndpoint (common)	Set the need for overriding the endpoint. This option needs to be used in combination with uriEndpointOverride option.	false	boolean
protocol (common)	The underlying protocol used to communicate with SQS.	https	String
proxyProtocol (common)	To define a proxy protocol when instantiating the SQS client. Enum values: • HTTP • HTTPS	HTTPS	Protocol
queueOwnerAWSAccountId (common)	Specify the queue owner aws account id when you need to connect the queue with different account owner.		String
region (common)	The region in which SQS client needs to work. When using this parameter, the configuration will expect the lowercase name of the region (for example ap-east-1) You'll need to use the name Region.EU_WEST_1.id().		String
trustAllCertificates (common)	If we want to trust all certificates in case of overriding the endpoint.	false	boolean
uriEndpointOverride (common)	Set the overriding uri endpoint. This option needs to be used in combination with overrideEndpoint option.		String
useDefaultCredentialsProvider (common)	Set whether the SQS client should expect to load credentials on an AWS infra instance or to expect static credentials to be passed in.	false	boolean
attributeNames (consumer)	A list of attribute names to receive when consuming. Multiple names can be separated by comma.		String

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
concurrentConsumers (consumer)	Allows you to use multiple threads to poll the sqs queue to increase throughput.	1	int
defaultVisibilityTimeout (consumer)	The default visibility timeout (in seconds).		Integer
deleteAfterRead (consumer)	Delete message from SQS after it has been read.	true	boolean
deleteIfFiltered (consumer)	Whether or not to send the DeleteMessage to the SQS queue if the exchange has property with key <code>Sqs2Constants#SQS_DELETE_FILTERED</code> (CamelAwsSqsDeleteFiltered) set to true.	true	boolean
extendMessageVisibility (consumer)	If enabled then a scheduled background task will keep extending the message visibility on SQS. This is needed if it takes a long time to process the message. If set to true defaultVisibilityTimeout must be set. See details at Amazon docs.	false	boolean
kmsDataKeyReusePeriodSeconds (consumer)	The length of time, in seconds, for which Amazon SQS can reuse a data key to encrypt or decrypt messages before calling AWS KMS again. An integer representing seconds, between 60 seconds (1 minute) and 86,400 seconds (24 hours). Default: 300 (5 minutes).		Integer
kmsMasterKeyId (consumer)	The ID of an AWS-managed customer master key (CMK) for Amazon SQS or a custom CMK.		String
maxMessagesPerPoll (consumer)	Gets the maximum number of messages as a limit to poll at each polling. Is default unlimited, but use 0 or negative number to disable it as unlimited.		int
messageAttributeNames (consumer)	A list of message attribute names to receive when consuming. Multiple names can be separated by comma.		String

Name	Description	Default	Type
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean
serverSideEncryptionEnabled (consumer)	Define if Server Side Encryption is enabled or not on the queue.	false	boolean
visibilityTimeout (consumer)	The duration (in seconds) that the received messages are hidden from subsequent retrieve requests after being retrieved by a <code>ReceiveMessage</code> request to set in the <code>com.amazonaws.services.sqs.model.SetQueueAttributesRequest</code> . This only make sense if its different from <code>defaultVisibilityTimeout</code> . It changes the queue visibility timeout attribute permanently.		Integer
waitTimeSeconds (consumer)	Duration in seconds (0 to 20) that the <code>ReceiveMessage</code> action call will wait until a message is in the queue to include in the response.		Integer
exceptionHandler (consumer (advanced))	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at <code>WARN</code> or <code>ERROR</code> level and ignored.		<code>ExceptionHandler</code>
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • <code>InOnly</code> • <code>InOut</code> • <code>InOptionalOut</code>		<code>ExchangePattern</code>
pollStrategy (consumer (advanced))	A pluggable <code>org.apache.camel.PollingConsumerPollingStrategy</code> allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an <code>Exchange</code> have been created and being routed in Camel.		<code>PollingConsumerPollStrategy</code>
batchSeparator (producer)	Set the separator when passing a <code>String</code> to send batch message operation.	,	<code>String</code>

Name	Description	Default	Type
delaySeconds (producer)	Delay sending messages for a number of seconds.		Integer
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
messageDeduplicationIdStrategy (producer)	Only for FIFO queues. Strategy for setting the messageDeduplicationId on the message. Can be one of the following options: useExchangeId, useContentBasedDeduplication. For the useContentBasedDeduplication option, no messageDeduplicationId will be set on the message. Enum values: ● useExchangeId ● useContentBasedDeduplication	useExchangeId	String
messageGroupIdStrategy (producer)	Only for FIFO queues. Strategy for setting the messageGroupId on the message. Can be one of the following options: useConstant, useExchangeId, usePropertyValue. For the usePropertyValue option, the value of property CamelAwsMessageGroupId will be used. Enum values: ● useConstant ● useExchangeId ● usePropertyValue		String

Name	Description	Default	Type
operation (producer)	The operation to do in case the user don't want to send only a message. Enum values: ● <code>sendBatchMessage</code> ● <code>deleteMessage</code> ● <code>listQueues</code> ● <code>purgeQueue</code> ● <code>deleteQueue</code>		<code>Sqs2Operations</code>
delayQueue (advanced)	Define if you want to apply <code>delaySeconds</code> option to the queue or on single messages.	<code>false</code>	<code>boolean</code>
queueUrl (advanced)	To define the <code>queueUrl</code> explicitly. All other parameters, which would influence the <code>queueUrl</code> , are ignored. This parameter is intended to be used, to connect to a mock implementation of SQS, for testing purposes.		<code>String</code>
proxyHost (proxy)	To define a proxy host when instantiating the SQS client.		<code>String</code>
proxyPort (proxy)	To define a proxy port when instantiating the SQS client.		<code>Integer</code>
maximumMessageSize (queue)	The <code>maximumMessageSize</code> (in bytes) an SQS message can contain for this queue.		<code>Integer</code>
messageRetentionPeriod (queue)	The <code>messageRetentionPeriod</code> (in seconds) a message will be retained by SQS for this queue.		<code>Integer</code>
policy (queue)	The policy for this queue. It can be loaded by default from classpath, but you can prefix with <code>classpath:</code> , <code>file:</code> , or <code>http:</code> to load the resource from different systems.		<code>String</code>
receiveMessageWaitTimeSeconds (queue)	If you do not specify <code>WaitTimeSeconds</code> in the request, the queue attribute <code>ReceiveMessageWaitTimeSeconds</code> is used to determine how long to wait.		<code>Integer</code>
redrivePolicy (queue)	Specify the policy that send message to DeadLetter queue. See detail at Amazon docs.		<code>String</code>

Name	Description	Default	Type
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.		int
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.		int
delay (scheduler)	Milliseconds before the next poll.	500	long
greedy (scheduler)	If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts.	1000	long
repeatCount (scheduler)	Specifies a maximum limit of number of fires. So if you set it to 1, the scheduler will only fire once. If you set it to 5, it will only fire five times. A value of zero or negative means fire forever.	0	long
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that. Enum values: ● TRACE ● DEBUG ● INFO ● WARN ● ERROR ● OFF	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService

Name	Description	Default	Type
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz component. Use value spring or quartz for built in scheduler.	none	Object
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for initialDelay and delay options. Enum values: • NANOSECONDS • MICROSECONDS • MILLISECONDS • SECONDS • MINUTES • HOURS • DAYS	MILLISECONDS	TimeUnit
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.	true	boolean
accessKey (security)	Amazon AWS Access Key.		String
secretKey (security)	Amazon AWS Secret Key.		String

Required SQS component options

You have to provide the `amazonSQSClient` in the Registry or your `accessKey` and `secretKey` to access the [Amazon's SQS](#).

11.6. BATCH CONSUMER

This component implements the Batch Consumer.

This allows you for instance to know how many messages exists in this batch and for instance let the Aggregator aggregate this number of messages.

11.7. USAGE

11.7.1. Static credentials vs Default Credential Provider

You have the possibility of avoiding the usage of explicit static credentials, by specifying the **useDefaultCredentialsProvider** option and set it to true.

- Java system properties - **aws.accessKeyId** and **aws.secretKey**
- Environment variables - **AWS_ACCESS_KEY_ID** and **AWS_SECRET_ACCESS_KEY**.
- Web Identity Token from AWS STS.
- The shared credentials and config files.
- Amazon ECS container credentials - loaded from the Amazon ECS if the environment variable **AWS_CONTAINER_CREDENTIALS_RELATIVE_URI** is set.
- Amazon EC2 Instance profile credentials.

For more information about this you can look at [AWS credentials documentation](#)

11.7.2. Message headers set by the SQS producer

Header	Type	Description
CamelAwsSqsMD5OfBody	String	The MD5 checksum of the Amazon SQS message.
CamelAwsSqsMessageId	String	The Amazon SQS message ID.
CamelAwsSqsDelaySeconds	Integer	The delay seconds that the Amazon SQS message can be seen by others.

11.7.3. Message headers set by the SQS consumer

Header	Type	Description
CamelAwsSqsMD5OfBody	String	The MD5 checksum of the Amazon SQS message.
CamelAwsSqsMessageId	String	The Amazon SQS message ID.
CamelAwsSqsReceiptHandle	String	The Amazon SQS message receipt handle.
CamelAwsSqsMessageAttributes	Map<String, String>	The Amazon SQS message attributes.

11.7.4. Advanced AmazonSQS configuration

If your Camel Application is running behind a firewall or if you need to have more control over the **SqsClient** instance configuration, you can create your own instance:

```
from("aws2-sqs://MyQueue?amazonSQSClient=#client&delay=5000&maxMessagesPerPoll=5")
.to("mock:result");
```

11.7.5. Creating or updating an SQS Queue

In the SQS Component, when an endpoint is started, a check is executed to obtain information about the existence of the queue or not. You're able to customize the creation through the **QueueAttributeName** mapping with the **SQSConfiguration** option.

```
from("aws2-sqs://MyQueue?amazonSQSClient=#client&delay=5000&maxMessagesPerPoll=5")
.to("mock:result");
```

In this example if the **MyQueue** queue is not already created on AWS (and the **autoCreateQueue** option is set to true), it will be created with default parameters from the SQS configuration. If it's already up on AWS, the SQS configuration options will be used to override the existent AWS configuration.

11.7.6. DelayQueue VS Delay for Single message

When the option **delayQueue** is set to true, the SQS Queue will be a **DelayQueue** with the **DelaySeconds** option as delay. For more information about **DelayQueue** you can read the [AWS SQS documentation](#). One important information to take into account is the following:

- For standard queues, the per-queue delay setting is not retroactive—changing the setting doesn't affect the delay of messages already in the queue.
- For FIFO queues, the per-queue delay setting is retroactive—changing the setting affects the delay of messages already in the queue.

as stated in the official documentation. If you want to specify a delay on single messages, you can ignore the **delayQueue** option, while you can set this option to true, if you need to add a fixed delay to all messages enqueued.

11.7.7. Server Side Encryption

There is a set of Server Side Encryption attributes for a queue. The related options are **serverSideEncryptionEnabled**, **keyMasterKeyId** and **kmsDataKeyReusePeriod**. The SSE is disabled by default. You need to explicitly set the option to true and set the related parameters as queue attributes.

11.8. JMS-STYLE SELECTORS

SQS does not allow selectors, but you can effectively achieve this by using the Camel Filter EIP and setting an appropriate **visibilityTimeout**. When SQS dispatches a message, it will wait up to the visibility timeout before it will try to dispatch the message to a different consumer unless a **DeleteMessage** is received. By default, Camel will always send the **DeleteMessage** at the end of the route, unless the route ended in failure. To achieve appropriate filtering and not send the **DeleteMessage** even on successful completion of the route, use a Filter:

■

```

from("aws2-sqs://MyQueue?
amazonSQSClient=#client&defaultVisibilityTimeout=5000&deleteIfFiltered=false&deleteAfterRead=false
")
.filter("${header.login} == true")
.setProperty(Sqs2Constants.SQS_DELETE_FILTERED, constant(true))
.to("mock:filter");

```

In the above code, if an exchange doesn't have an appropriate header, it will not make it through the filter AND also not be deleted from the SQS queue. After 5000 milliseconds, the message will become visible to other consumers.

Note we must set the property **Sqs2Constants.SQS_DELETE_FILTERED** to **true** to instruct Camel to send the **DeleteMessage**, if being filtered.

11.9. AVAILABLE PRODUCER OPERATIONS

- single message (default)
- `sendBatchMessage`
- `deleteMessage`
- `listQueues`

11.10. SEND MESSAGE

You can set a **SendMessageBatchRequest** or an **Iterable**

```

from("direct:start")
.setBody(constant("Camel rocks!"))
.to("aws2-sqs://camel-1?accessKey=RAW(XXX)&secretKey=RAW(XXX)&region=eu-west-1");

```

11.11. SEND BATCH MESSAGE

You can set a **SendMessageBatchRequest** or an **Iterable**

```

from("direct:start")
.setHeader(SqsConstants.SQS_OPERATION, constant("sendBatchMessage"))
.process(new Processor() {
    @Override
    public void process(Exchange exchange) throws Exception {
        Collection c = new ArrayList();
        c.add("team1");
        c.add("team2");
        c.add("team3");
        c.add("team4");
        exchange.getIn().setBody(c);
    }
})
.to("aws2-sqs://camel-1?accessKey=RAW(XXX)&secretKey=RAW(XXX)&region=eu-west-1");

```

As result you'll get an exchange containing a **SendMessageBatchResponse** instance, that you can examine to check what messages were successful and what not. The id set on each message of the batch will be a Random UUID.

11.12. DELETE SINGLE MESSAGE

Use **deleteMessage** operation to delete a single message. You'll need to set a receipt handle header for the message you want to delete.

```
from("direct:start")
  .setHeader(SqsConstants.SQS_OPERATION, constant("deleteMessage"))
  .setHeader(SqsConstants.RECEIPT_HANDLE, constant("123456"))
  .to("aws2-sqs://camel-1?accessKey=RAW(XXX)&secretKey=RAW(XXX)&region=eu-west-1");
```

As result you'll get an exchange containing a **DeleteMessageResponse** instance, that you can use to check if the message was deleted or not.

11.13. LIST QUEUES

Use **listQueues** operation to list queues.

```
from("direct:start")
  .setHeader(SqsConstants.SQS_OPERATION, constant("listQueues"))
  .to("aws2-sqs://camel-1?accessKey=RAW(XXX)&secretKey=RAW(XXX)&region=eu-west-1");
```

As result you'll get an exchange containing a **ListQueuesResponse** instance, that you can examine to check the actual queues.

11.14. PURGE QUEUE

Use **purgeQueue** operation to purge queue.

```
from("direct:start")
  .setHeader(SqsConstants.SQS_OPERATION, constant("purgeQueue"))
  .to("aws2-sqs://camel-1?accessKey=RAW(XXX)&secretKey=RAW(XXX)&region=eu-west-1");
```

As result you'll get an exchange containing a **PurgeQueueResponse** instance.

11.15. QUEUE AUTOCREATION

With the option **autoCreateQueue** users are able to avoid the autocreation of an SQS Queue in case it doesn't exist. The default for this option is **true**. If set to false any operation on a not-existent queue in AWS won't be successful and an error will be returned.

11.16. SEND BATCH MESSAGE AND MESSAGE DEDUPLICATION STRATEGY

In case you're using a **SendBatchMessage** Operation, you can set two different kind of Message Deduplication Strategy: - useExchangeId - useContentBasedDeduplication

The first one will use a **ExchangeIdMessageDeduplicationIdStrategy**, that will use the Exchange ID as parameter. The other one will use a **NullMessageDeduplicationIdStrategy**, that will use the body as deduplication element.

In case of send batch message operation, you'll need to use the **useContentBasedDeduplication** and on the Queue you're pointing you'll need to enable the **content based deduplication** option.

11.17. DEPENDENCIES

Maven users will need to add the following dependency to their pom.xml.

pom.xml

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-aws2-sqs</artifactId>
  <version>${camel-version}</version>
</dependency>
```

where **{camel-version}** must be replaced by the actual version of Camel.

11.18. SPRING BOOT AUTO-CONFIGURATION

The component supports 44 options, which are listed below.

Name	Description	Default	Type
camel.component.aws2-sqs.access-key	Amazon AWS Access Key.		String
camel.component.aws2-sqs.amazon-aws-host	The hostname of the Amazon AWS cloud.	amazonaws.com	String
camel.component.aws2-sqs.amazon-sqs-client	To use the AmazonSQS as client. The option is a software.amazon.awssdk.services.sqs.SqsClient type.		SqsClient
camel.component.aws2-sqs.attribute-names	A list of attribute names to receive when consuming. Multiple names can be separated by comma.		String
camel.component.aws2-sqs.auto-create-queue	Setting the autocreation of the queue.	false	Boolean

Name	Description	Default	Type
<code>camel.component.aws2-sqs.autowired-enabled</code>	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
<code>camel.component.aws2-sqs.batch-separator</code>	Set the separator when passing a String to send batch message operation.	,	String
<code>camel.component.aws2-sqs.bridge-error-handler</code>	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
<code>camel.component.aws2-sqs.concurrent-consumers</code>	Allows you to use multiple threads to poll the sqs queue to increase throughput.	1	Integer
<code>camel.component.aws2-sqs.configuration</code>	The AWS SQS default configuration. The option is a <code>org.apache.camel.component.aws2.sqs.Sqs2Configuration</code> type.		Sqs2Configuration
<code>camel.component.aws2-sqs.default-visibility-timeout</code>	The default visibility timeout (in seconds).		Integer
<code>camel.component.aws2-sqs.delay-queue</code>	Define if you want to apply <code>delaySeconds</code> option to the queue or on single messages.	false	Boolean
<code>camel.component.aws2-sqs.delay-seconds</code>	Delay sending messages for a number of seconds.		Integer
<code>camel.component.aws2-sqs.delete-after-read</code>	Delete message from SQS after it has been read.	true	Boolean

Name	Description	Default	Type
<code>camel.component.aws2-sqs.delete-if-filtered</code>	Whether or not to send the DeleteMessage to the SQS queue if the exchange has property with key <code>Sqs2Constants#SQS_DELETE_FILTERED</code> (CamelAwsSqsDeleteFiltered) set to true.	true	Boolean
<code>camel.component.aws2-sqs.enabled</code>	Whether to enable auto configuration of the aws2-sqs component. This is enabled by default.		Boolean
<code>camel.component.aws2-sqs.extend-message-visibility</code>	If enabled then a scheduled background task will keep extending the message visibility on SQS. This is needed if it takes a long time to process the message. If set to true <code>defaultVisibilityTimeout</code> must be set. See details at Amazon docs.	false	Boolean
<code>camel.component.aws2-sqs.kms-data-key-reuse-period-seconds</code>	The length of time, in seconds, for which Amazon SQS can reuse a data key to encrypt or decrypt messages before calling AWS KMS again. An integer representing seconds, between 60 seconds (1 minute) and 86,400 seconds (24 hours). Default: 300 (5 minutes).		Integer
<code>camel.component.aws2-sqs.kms-master-key-id</code>	The ID of an AWS-managed customer master key (CMK) for Amazon SQS or a custom CMK.		String
<code>camel.component.aws2-sqs.lazy-start-producer</code>	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
<code>camel.component.aws2-sqs.maximum-message-size</code>	The <code>maximumMessageSize</code> (in bytes) an SQS message can contain for this queue.		Integer
<code>camel.component.aws2-sqs.message-attribute-names</code>	A list of message attribute names to receive when consuming. Multiple names can be separated by comma.		String

Name	Description	Default	Type
<code>camel.component.aws2-sqs.message-deduplication-id-strategy</code>	Only for FIFO queues. Strategy for setting the <code>messageDeduplicationId</code> on the message. Can be one of the following options: <code>useExchangeId</code> , <code>useContentBasedDeduplication</code> . For the <code>useContentBasedDeduplication</code> option, no <code>messageDeduplicationId</code> will be set on the message.	<code>useExchangeId</code>	String
<code>camel.component.aws2-sqs.message-group-id-strategy</code>	Only for FIFO queues. Strategy for setting the <code>messageGroupId</code> on the message. Can be one of the following options: <code>useConstant</code> , <code>useExchangeId</code> , <code>usePropertyValue</code> . For the <code>usePropertyValue</code> option, the value of property <code>CamelAwsMessageGroupId</code> will be used.		String
<code>camel.component.aws2-sqs.message-retention-period</code>	The <code>messageRetentionPeriod</code> (in seconds) a message will be retained by SQS for this queue.		Integer
<code>camel.component.aws2-sqs.operation</code>	The operation to do in case the user don't want to send only a message.		<code>Sqs2Operations</code>
<code>camel.component.aws2-sqs.override-endpoint</code>	Set the need for overriding the endpoint. This option needs to be used in combination with <code>uriEndpointOverride</code> option.	<code>false</code>	Boolean
<code>camel.component.aws2-sqs.policy</code>	The policy for this queue. It can be loaded by default from classpath, but you can prefix with <code>classpath:</code> , <code>file:</code> , or <code>http:</code> to load the resource from different systems.		String
<code>camel.component.aws2-sqs.protocol</code>	The underlying protocol used to communicate with SQS.	<code>https</code>	String
<code>camel.component.aws2-sqs.proxy-host</code>	To define a proxy host when instantiating the SQS client.		String
<code>camel.component.aws2-sqs.proxy-port</code>	To define a proxy port when instantiating the SQS client.		Integer

Name	Description	Default	Type
<code>camel.component.aws2-sqs.proxy-protocol</code>	To define a proxy protocol when instantiating the SQS client.		Protocol
<code>camel.component.aws2-sqs.queue-owner-a-w-s-account-id</code>	Specify the queue owner aws account id when you need to connect the queue with different account owner.		String
<code>camel.component.aws2-sqs.queue-url</code>	To define the queueUrl explicitly. All other parameters, which would influence the queueUrl, are ignored. This parameter is intended to be used, to connect to a mock implementation of SQS, for testing purposes.		String
<code>camel.component.aws2-sqs.receive-message-wait-time-seconds</code>	If you do not specify WaitTimeSeconds in the request, the queue attribute ReceiveMessageWaitTimeSeconds is used to determine how long to wait.		Integer
<code>camel.component.aws2-sqs.redrive-policy</code>	Specify the policy that send message to DeadLetter queue. See detail at Amazon docs.		String
<code>camel.component.aws2-sqs.region</code>	The region in which SQS client needs to work. When using this parameter, the configuration will expect the lowercase name of the region (for example ap-east-1) You'll need to use the name Region.EU_WEST_1.id().		String
<code>camel.component.aws2-sqs.secret-key</code>	Amazon AWS Secret Key.		String
<code>camel.component.aws2-sqs.server-side-encryption-enabled</code>	Define if Server Side Encryption is enabled or not on the queue.	false	Boolean
<code>camel.component.aws2-sqs.trust-all-certificates</code>	If we want to trust all certificates in case of overriding the endpoint.	false	Boolean
<code>camel.component.aws2-sqs.uri-endpoint-override</code>	Set the overriding uri endpoint. This option needs to be used in combination with overrideEndpoint option.		String

Name	Description	Default	Type
<code>camel.component.aws2-sqs.use-default-credentials-provider</code>	Set whether the SQS client should expect to load credentials on an AWS infra instance or to expect static credentials to be passed in.	false	Boolean
<code>camel.component.aws2-sqs.visibility-timeout</code>	The duration (in seconds) that the received messages are hidden from subsequent retrieve requests after being retrieved by a <code>ReceiveMessage</code> request to set in the <code>com.amazonaws.services.sqs.model.SetQueueAttributesRequest</code> . This only make sense if its different from <code>defaultVisibilityTimeout</code> . It changes the queue visibility timeout attribute permanently.		Integer
<code>camel.component.aws2-sqs.wait-time-seconds</code>	Duration in seconds (0 to 20) that the <code>ReceiveMessage</code> action call will wait until a message is in the queue to include in the response.		Integer

CHAPTER 12. AWS SECRETS MANAGER

Only producer is supported

The AWS Secrets Manager component supports [AWS Secrets Manager](#) service.

Prerequisites

You must have a valid Amazon Web Services developer account, and be signed up to use Amazon Secrets Manager. More information is available at [AWS Secrets Manager](#).

12.1. DEPENDENCIES

When using **camel-aws-secrets-manager** with Red Hat build of Camel Spring Boot, add the following Maven dependency to your **pom.xml** to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-aws-secrets-manager-starter</artifactId>
</dependency>
```

12.2. URI FORMAT

```
aws-secrets-manager://label[?options]
```

You can append query options to the URI in the following format:

```
`?options=value&option2=value&...`
```

12.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

12.3.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).
- directly in the Java code.

12.3.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

12.4. COMPONENT OPTIONS

The AWS Secrets Manager component supports 23 options, which are listed below.

Name	Description	Default	Type
binaryPayload (producer)	Set if the secret is binary or not.	false	boolean
configuration (producer)	Component configuration.		SecretsManagerConfiguration
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

Name	Description	Default	Type
operation (producer)	Required The operation to perform. Enum values: • listSecrets • createSecret • getSecret • describeSecret • deleteSecret • rotateSecret • updateSecret • restoreSecret • replicateSecretToRegions		SecretsManagerOperations
overrideEndpoint (producer)	Set the need for overriding the endpoint. This option needs to be used in combination with the uriEndpointOverride option.	false	boolean
pojoRequest (producer)	If we want to use a POJO request as body or not.	false	boolean
profileCredentialsName (producer)	If using a profile credentials provider, this parameter will set the profile name.		String
region (producer)	The region in which a Secrets Manager client needs to work. When using this parameter, the configuration will expect the lowercase name of the region (for example, ap-east-1) You'll need to use the name Region.EU_WEST_1.id(). Enum values: • ap-south-2 • ap-south-1 • eu-south-1 • eu-south-2 • us-gov-east-1 • me-central-1 • il-central-1 • ca-central-1		String

Name	● eu-central-1 ● us-iso-west-1 Description	Default	Type
	● eu-central-2 ● eu-isoe-west-1 ● us-west-1 ● us-west-2 ● af-south-1 ● eu-north-1 ● eu-west-3 ● eu-west-2 ● eu-west-1 ● ap-northeast-3 ● ap-northeast-2 ● ap-northeast-1 ● me-south-1 ● sa-east-1 ● ap-east-1 ● cn-north-1 ● ca-west-1 ● us-gov-west-1 ● ap-southeast-1 ● ap-southeast-2 ● us-iso-east-1 ● ap-southeast-3 ● ap-southeast-4 ● us-east-1 ● us-east-2 ● cn-northwest-1 ● us-isob-east-1 ● aws-global ● aws-cn-global ● aws-us-gov-global ● aws-iso-global		

Name	aws-iso-b-global Description	Default	Type
uriEndpointOverride (producer)	Set the overriding uri endpoint. This option needs to be used in combination with <code>overrideEndpoint</code> option.	<code>true</code>	String
useProfileCredentialsProvider (producer)	Set whether the Secrets Manager client should expect to load credentials through a profile credentials provider.	<code>false</code>	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	<code>true</code>	boolean
secretsManagerClient (advanced)	Autowired To use an existing configured AWS Secrets Manager client.		SecretsManagerClient
healthCheckConsumerEnabled (health)	Used for enabling or disabling all consumer based health checks from this component.	<code>true</code>	boolean
healthCheckProducerEnabled (health)	Used for enabling or disabling all producer based health checks from this component. Notice: Camel has by default disabled all producer based health-checks. You can turn on producer checks globally by setting <code>camel.health.producersEnabled=true</code> .	<code>true</code>	boolean
proxyHost (proxy)	To define a proxy host when instantiating the Secrets Manager client.		String
proxyPort (proxy)	To define a proxy port when instantiating the Secrets Manager client.		Integer
proxyProtocol (proxy)	To define a proxy protocol when instantiating the Secrets Manager client. Enum values: - HTTP - HTTPS	HTTPS	Protocol
accessKey (security)	Amazon AWS Access Key.		String
secretKey (security)	Amazon AWS Secret Key.		String

Name	Description	Default	Type
sessionToken (security)	Amazon AWS Session Token used when the user needs to assume an IAM role.		String
trustAllCertificates (security)	If we want to trust all certificates in case of overriding the endpoint.	false	boolean
useDefaultCredentialsProvider (security)	Set whether the Translate client should expect to load credentials through a default credentials provider or to expect static credentials to be passed in.	false	boolean
useSessionCredentials (security)	Set whether the Secrets Manager client should expect to use Session Credentials. This is useful in a situation in which the user needs to assume an IAM role for doing operations in Secrets Manager.	false	boolean

12.5. ENDPOINT OPTIONS

The AWS Secrets Manager endpoint is configured using URI syntax:

```
aws-secrets-manager:label
```

With the following *path* and *query* parameters:

12.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
label (producer)	Required Logical name.		String

12.5.2. Query Parameters (19 parameters)

Name	Description	Default	Type
binaryPayload (producer)	Set if the secret is binary or not.	false	boolean

Name	Description	Default	Type
operation (producer)	Required The operation to perform. Enum values: • listSecrets • createSecret • getSecret • describeSecret • deleteSecret • rotateSecret • updateSecret • restoreSecret • replicateSecretToRegions		SecretsManagerOperations
overrideEndpoint (producer)	Set the need for overriding the endpoint. This option needs to be used in combination with the uriEndpointOverride option.	false	boolean
pojoRequest (producer)	If we want to use a POJO request as body or not.	false	boolean
profileCredentialsName (producer)	If using a profile credentials provider, this parameter will set the profile name.		String
region (producer)	The region in which a Secrets Manager client needs to work. When using this parameter, the configuration will expect the lowercase name of the region (for example, ap-east-1) You'll need to use the name Region.EU_WEST_1.id(). Enum values:		String

Name	Description	Default	Type
	● ap-south-2 ● ap-south-1 ● eu-south-1 ● eu-south-2 ● us-gov-east-1 ● me-central-1 ● il-central-1 ● ca-central-1 ● eu-central-1 ● us-iso-west-1 ● eu-central-2 ● eu-isoe-west-1 ● us-west-1 ● us-west-2 ● af-south-1 ● eu-north-1 ● eu-west-3 ● eu-west-2 ● eu-west-1 ● ap-northeast-3 ● ap-northeast-2 ● ap-northeast-1 ● me-south-1 ● sa-east-1 ● ap-east-1 ● cn-north-1 ● ca-west-1 ● us-gov-west-1 ● ap-southeast-1 ● ap-southeast-2 ● us-iso-east-1 ● ap-southeast-3		

Name	• ap-southeast-1 Description	Default	Type
	• us-east-1 • us-east-2 • cn-northwest-1 • us-isob-east-1 • aws-global • aws-cn-global • aws-us-gov-global • aws-iso-global • aws-iso-b-global		
uriEndpointOverride (producer)	Set the overriding uri endpoint. This option needs to be used in combination with <code>overrideEndpoint</code> option.		String
useProfileCredentialsProvider (producer)	Set whether the Secrets Manager client should expect to load credentials through a profile credentials provider.	false	boolean

Name	Description	Default	Type
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
secretsManagerClient (advanced)	Autowired To use an existing configured AWS Secrets Manager client.		SecretsManagerClient
proxyHost (proxy)	To define a proxy host when instantiating the Secrets Manager client.		String
proxyPort (proxy)	To define a proxy port when instantiating the Secrets Manager client.		Integer
proxyProtocol (proxy)	To define a proxy protocol when instantiating the Secrets Manager client. Enum values: ● HTTP ● HTTPS	HTTPS	Protocol

Name	Description	Default	Type
accessKey (security)	Amazon AWS Access Key.		String
secretKey (security)	Amazon AWS Secret Key.		String
sessionToken (security)	Amazon AWS Session Token used when the user needs to assume an IAM role.		String
trustAllCertificates (security)	If we want to trust all certificates in case of overriding the endpoint.	false	boolean
useDefaultCredentialsProvider (security)	Set whether the Translate client should expect to load credentials through a default credentials provider or to expect static credentials to be passed in.	false	boolean
useSessionCredentials (security)	Set whether the Secrets Manager client should expect to use Session Credentials. This is useful in a situation in which the user needs to assume an IAM role for doing operations in Secrets Manager.	false	boolean

12.5.3. Static credentials, Default Credential Provider and Profile Credentials Provider

You can avoid the usage of explicit static credentials by specifying the **useDefaultCredentialsProvider** option and setting it to **true**.

The order of evaluation for Default Credentials Provider is as per the following:

- Java system properties - **aws.accessKeyId** and **aws.secretKey**.
- Environment variables - **AWS_ACCESS_KEY_ID** and **AWS_SECRET_ACCESS_KEY**.
- Web Identity Token from AWS STS.
- The shared credentials and config files.

- Amazon ECS container credentials - loaded from the Amazon ECS if the environment variable **AWS_CONTAINER_CREDENTIALS_RELATIVE_URI** is set.
- Amazon EC2 Instance profile credentials.

You can use the Profile Credentials Provider, by specifying the **useProfileCredentialsProvider** option to true and **profileCredentialsName** to the profile name.

Only one of static, default and profile credentials could be used at the same time. For more information about this, see [AWS credentials documentation](#).

12.5.4. Using AWS Secrets Manager Property Function

To use this function, you need to provide credentials to AWS Secrets Manager Service as environment variables:

```
export CAMEL_VAULT_AWS_ACCESS_KEY=accessKey
export CAMEL_VAULT_AWS_SECRET_KEY=secretKey
export CAMEL_VAULT_AWS_REGION=region
```

You can also configure the credentials in the **application.properties** file such as:

```
camel.vault.aws.accessKey = accessKey
camel.vault.aws.secretKey = secretKey
camel.vault.aws.region = region
```

If you want to use the [AWS default credentials provider](#) instead, you need to provide the following env variables:

```
export CAMEL_VAULT_AWS_USE_DEFAULT_CREDENTIALS_PROVIDER=true
export CAMEL_VAULT_AWS_REGION=region
```

You can also configure the credentials in the **application.properties** file such as:

```
camel.vault.aws.defaultCredentialsProvider = true
camel.vault.aws.region = region
```

It is also possible to specify a particular profile name for accessing AWS Secrets Manager as follows:

```
export CAMEL_VAULT_AWS_USE_PROFILE_CREDENTIALS_PROVIDER=true
export CAMEL_VAULT_AWS_PROFILE_NAME=test-account
export CAMEL_VAULT_AWS_REGION=region
```

You can also configure the credentials in the **application.properties** file such as:

```
camel.vault.aws.profileCredentialsProvider = true
camel.vault.aws.profileName = test-account
camel.vault.aws.region = region
```

NOTE

camel.vault.aws configuration only applies to the AWS Secrets Manager properties function (for example, when resolving properties). When using the **operation** option to create, get, list secrets etc., provide the usual options for connecting to AWS Services.

At this point, you can reference a property in the following way:

```
<camelContext>
  <route>
    <from uri="direct:start"/>
    <to uri="{{aws:route}}"/>
  </route>
</camelContext>
```

Where the route will be the name of the secret stored in the AWS Secrets Manager Service.

You could specify a default value in case the secret is not present on AWS Secret Manager:

```
<camelContext>
  <route>
    <from uri="direct:start"/>
    <to uri="{{aws:route:default}}"/>
  </route>
</camelContext>
```

In this case, if the secret doesn't exist, the property will fall back to "default" as value.

Also, you are able to get a particular field of the secret, if you have, for example, a secret named database of this form:

```
{
  "username": "admin",
  "password": "password123",
  "engine": "postgres",
  "host": "127.0.0.1",
  "port": "3128",
  "dbname": "db"
}
```

You can get a single secret value in your route as follows:

```
<camelContext>
  <route>
    <from uri="direct:start"/>
    <log message="Username is {{aws:database/username}}"/>
  </route>
</camelContext>
```

Or re-use the property as part of an endpoint.

You can specify a default value in case the particular field of secret is not present on AWS Secret Manager:

```
<camelContext>
  <route>
    <from uri="direct:start"/>
    <log message="Username is {{aws:database/username:admin}}"/>
  </route>
</camelContext>
```

In this case, if the secret does not exist or the secret exists, but the username field is not part of the secret, the property will fall back to "admin" as its value.

There is also the syntax to get a particular version of the secret for both the approach, with field/default value specified or only with secret:

```
<camelContext>
  <route>
    <from uri="direct:start"/>
    <to uri="{{aws:route@bf9b4f4b-8e63-43fd-a73c-3e2d3748b451}}"/>
  </route>
</camelContext>
```

This approach will return the RAW route secret with the version 'bf9b4f4b-8e63-43fd-a73c-3e2d3748b451'.

```
<camelContext>
  <route>
    <from uri="direct:start"/>
    <to uri="{{aws:route:default@bf9b4f4b-8e63-43fd-a73c-3e2d3748b451}}"/>
  </route>
</camelContext>
```

This approach will return the route secret value with version 'bf9b4f4b-8e63-43fd-a73c-3e2d3748b451' or default value in case the secret doesn't exist or the version doesn't exist.

```
<camelContext>
  <route>
    <from uri="direct:start"/>
    <log message="Username is {{aws:database/username:admin@bf9b4f4b-8e63-43fd-a73c-3e2d3748b451}}"/>
  </route>
</camelContext>
```

This approach will return the username field of the database secret with version 'bf9b4f4b-8e63-43fd-a73c-3e2d3748b451' or admin in case the secret doesn't exist or the version doesn't exist.

The only requirement is adding the camel-aws-secrets-manager jar to your Camel application.

12.5.5. Automatic Camel context reloading on Secret Refresh

Being able to reload Camel context on a Secret Refresh could be done by specifying the usual credentials (the same used for AWS Secret Manager Property Function).

With Environment variables:

```
export CAMEL_VAULT_AWS_USE_DEFAULT_CREDENTIALS_PROVIDER=accessKey
export CAMEL_VAULT_AWS_REGION=region
```

or as plain Camel main properties:

```
camel.vault.aws.useDefaultCredentialProvider = true
camel.vault.aws.region = region
```

Or by specifying `accessKey`/`SecretKey` and `region`, instead of using the default credentials provider chain.

To enable the automatic refresh, set the additional properties as follows:

```
camel.vault.aws.refreshEnabled=true
camel.vault.aws.refreshPeriod=60000
camel.vault.aws.secrets=Secret
camel.main.context-reload-enabled = true
```

where **`camel.vault.aws.refreshEnabled`** will enable the automatic context reload, **`camel.vault.aws.refreshPeriod`** is the interval of time between two different checks for update events and **`camel.vault.aws.secrets`** is a regex representing the secrets we want to track for updates.

Note that **`camel.vault.aws.secrets`** is not mandatory. If it is not specified, the task responsible for checking updates events will take it into accounts or the properties with an **`aws:`** prefix.

12.5.6. Automatic Camel context reloading on Secret Refresh with Eventbridge and AWS SQS Services

Another option is to use AWS EventBridge in conjunction with the AWS SQS service.

On the AWS side, the following resources need to be created:

- an AWS CloudTrail trail
- an AWS SQS Queue
- an Eventbridge rule of the following kind

```
{
  "source": ["aws.secretsmanager"],
  "detail-type": ["AWS API Call via CloudTrail"],
  "detail": {
    "eventSource": ["secretsmanager.amazonaws.com"]
  }
}
```

This rule will make the event related to AWS Secrets Manager filtered

- You need to set the a Rule target to the AWS SQS Queue for Eventbridge rule
- You need to give permission to the Eventbridge rule, to write on the above SQS Queue. For doing this you'll need to define a json file like this:

```
{
```

```
"Policy": "{ \"Version\": \"2012-10-17\", \"Id\": \"<queue_arn>/SQSDefaultPolicy\", \"Statement\":
[ { \"Sid\": \"EventsToMyQueue\", \"Effect\": \"Allow\", \"Principal\": { \"Service\":
\"events.amazonaws.com\" }, \"Action\": \"sqs:SendMessage\", \"Resource\": \"<queue_arn>\",
\"Condition\": { \"ArnEquals\": { \"aws:SourceArn\": \"<eventbridge_rule_arn>\" } } } ] }"
```

Change the values for **queue_arn** and **eventbridge_rule_arn** and save the file with **policy.json** name and run the following command with AWS CLI:

```
aws sqs set-queue-attributes --queue-url <queue_url> --attributes file://policy.json
```

where **queue_url** is the AWS SQS Queue URL of the just created Queue.

Now you should be able to set up the configuration on the Camel side. To enable the SQS notification add the following properties:

```
camel.vault.aws.refreshEnabled=true
camel.vault.aws.refreshPeriod=60000
camel.vault.aws.secrets=Secret
camel.main.context-reload-enabled = true
camel.vault.aws.useSqsNotification=true
camel.vault.aws.sqsQueueUrl=<queue_url>
```

where **queue_url** is the AWS SQS Queue URL of the just created Queue.

Whenever an event of **PutSecretValue** for the Secret named **Secret** happens, a message will be enqueued in the AWS SQS Queue and consumed on the Camel side and a context reload will be triggered.

12.6. MESSAGE HEADERS

The AWS Secrets Manager component supports 8 message header(s), which is/are listed below:

Name	Description	Default	Type
CamelAwsSecretsManagerOperation (producer) Constant: OPERATION	The operation we want to perform.		String
CamelAwsSecretsManagerMaxResults (producer) Constant: MAX_RESULTS	The number of results to include in the response.		Integer
CamelAwsSecretsManagerSecretName (producer) Constant: SECRET_NAME	The name of the secret.		String

Name	Description	Default	Type
CamelAwsSecretsManagerSecretDescription (producer) Constant: SECRET_DESCRIPTION	The description of the secret.		String
CamelAwsSecretsManagerSecretId (producer) Constant: SECRET_ID	The ARN or name of the secret.		String
CamelAwsSecretsManagerLambdaRotationFunctionArn (producer) Constant: LAMBDA_ROTATION_FUNCTION_ARN	The ARN of the Lambda rotation function that can rotate the secret.		String
CamelAwsSecretsManagerSecretVersionId (producer) Constant: SECRET_VERSION_ID	The unique identifier of the version of the secret.		String
CamelAwsSecretsManagerSecretReplicationRegions (producer) Constant: SECRET_REPLICATION_REGIONS	A comma separated list of Regions in which to replicate the secret.		String

12.6.1. Secrets Manager Producer operations

Camel-AWS-Secrets-manager component provides the following operation on the producer side:

- listSecrets
- createSecret
- deleteSecret
- describeSecret
- rotateSecret
- getSecret
- updateSecret

- `replicateSecretToRegions`

12.7. SPRING BOOT AUTO-CONFIGURATION

The component supports 24 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.aws-secrets-manager.access-key</code>	Amazon AWS Access Key.		String
<code>camel.component.aws-secrets-manager.autowired-enabled</code>	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
<code>camel.component.aws-secrets-manager.binary-payload</code>	Set if the secret is binary or not.	false	Boolean
<code>camel.component.aws-secrets-manager.configuration</code>	Component configuration. The option is a <code>org.apache.camel.component.aws.secretsmanager.SecretsManagerConfiguration</code> type.		SecretsManagerConfiguration
<code>camel.component.aws-secrets-manager.enabled</code>	Whether to enable auto configuration of the <code>aws-secrets-manager</code> component. This is enabled by default.		Boolean
<code>camel.component.aws-secrets-manager.health-check-consumer-enabled</code>	Used for enabling or disabling all consumer based health checks from this component.	true	Boolean
<code>camel.component.aws-secrets-manager.health-check-producer-enabled</code>	Used for enabling or disabling all producer based health checks from this component. Notice: Camel has by default disabled all producer based health-checks. You can turn on producer checks globally by setting <code>camel.health.producersEnabled=true</code> .	true	Boolean

Name	Description	Default	Type
<code>camel.component.aws-secrets-manager.lazy-start-producer</code>	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
<code>camel.component.aws-secrets-manager.operation</code>	The operation to perform.		SecretsManagerOperations
<code>camel.component.aws-secrets-manager.override-endpoint</code>	Set the need for overriding the endpoint. This option needs to be used in combination with the <code>uriEndpointOverride</code> option.	false	Boolean
<code>camel.component.aws-secrets-manager.pojo-request</code>	If we want to use a POJO request as body or not.	false	Boolean
<code>camel.component.aws-secrets-manager.profile-credentials-name</code>	If using a profile credentials provider, this parameter will set the profile name.		String
<code>camel.component.aws-secrets-manager.proxy-host</code>	To define a proxy host when instantiating the Secrets Manager client.		String
<code>camel.component.aws-secrets-manager.proxy-port</code>	To define a proxy port when instantiating the Secrets Manager client.		Integer
<code>camel.component.aws-secrets-manager.proxy-protocol</code>	To define a proxy protocol when instantiating the Secrets Manager client.		Protocol

Name	Description	Default	Type
<code>camel.component.aws-secrets-manager.region</code>	The region in which a Secrets Manager client needs to work. When using this parameter, the configuration will expect the lowercase name of the region (for example, ap-east-1) You'll need to use the name <code>Region.EU_WEST_1.id()</code> .		String
<code>camel.component.aws-secrets-manager.secret-key</code>	Amazon AWS Secret Key.		String
<code>camel.component.aws-secrets-manager.secrets-manager-client</code>	To use an existing configured AWS Secrets Manager client. The option is a <code>software.amazon.awssdk.services.secretsmanager.SecretsManagerClient</code> type.		SecretsManagerClient
<code>camel.component.aws-secrets-manager.session-token</code>	Amazon AWS Session Token used when the user needs to assume an IAM role.		String
<code>camel.component.aws-secrets-manager.trust-all-certificates</code>	If we want to trust all certificates in case of overriding the endpoint.	false	Boolean
<code>camel.component.aws-secrets-manager.uri-endpoint-override</code>	Set the overriding uri endpoint. This option needs to be used in combination with <code>overrideEndpoint</code> option.		String
<code>camel.component.aws-secrets-manager.use-default-credentials-provider</code>	Set whether the Translate client should expect to load credentials through a default credentials provider or to expect static credentials to be passed in.	false	Boolean
<code>camel.component.aws-secrets-manager.use-profile-credentials-provider</code>	Set whether the Secrets Manager client should expect to load credentials through a profile credentials provider.	false	Boolean

Name	Description	Default	Type
<code>camel.component.aws-secrets-manager.use-session-credentials</code>	Set whether the Secrets Manager client should expect to use Session Credentials. This is useful in a situation in which the user needs to assume an IAM role for doing operations in Secrets Manager.	false	Boolean

CHAPTER 13. AZURE KEY VAULT

Only producer is supported

The azure-key-vault component that integrates [Azure Key Vault](#).

Prerequisites

You must have a valid Windows Azure Key Vault account. More information is available at [Azure Documentation Portal](#).

13.1. DEPENDENCIES

When using **camel-azure-key-vault** with Red Hat build of Camel Spring Boot, add the following Maven dependency to your **pom.xml** to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-azure-key-vault-starter</artifactId>
</dependency>
```

13.2. URI FORMAT

```
azure-key-vault://vaultName[?options]
```

13.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

13.3.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).
- directly in the Java code.

13.3.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

13.4. COMPONENT OPTIONS

The Azure Key Vault component supports 2 options, which are listed below.

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

13.5. ENDPOINT OPTIONS

The Azure Key Vault endpoint is configured using URI syntax:

```
azure-key-vault:vaultName
```

With the following *path* and *query* parameters:

13.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
vaultName (producer)	Vault Name to be used.		String

13.5.2. Query Parameters (7 parameters)

Name	Description	Default	Type
credentialType (common)	Determines the credential strategy to adopt. Enum values: • CLIENT_SECRET • AZURE_IDENTITY	CLIENT_SECRET	CredentialType
operation (producer)	Operation to be performed. Enum values: • createSecret • getSecret • deleteSecret • purgeDeletedSecret		KeyVaultOperation
secretClient (producer)	Autowired Instance of Secret client.		SecretClient
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
clientId (security)	Client Id to be used.		String

Name	Description	Default	Type
clientSecret (security)	Client Secret to be used.		String
tenantId (security)	Tenant Id to be used.		String

13.6. USAGE

13.6.1. Using Azure Key Vault Property Function

To use this function, you'll need to provide credentials to Azure Key Vault Service as environment variables:

```
export $CAMEL_VAULT_AZURE_TENANT_ID=tenantId
export $CAMEL_VAULT_AZURE_CLIENT_ID=clientId
export $CAMEL_VAULT_AZURE_CLIENT_SECRET=clientSecret
export $CAMEL_VAULT_AZURE_VAULT_NAME=vaultName
```

You can also configure the credentials in the **application.properties** file such as:

```
camel.vault.azure.tenantId = accessKey
camel.vault.azure.clientId = clientId
camel.vault.azure.clientSecret = clientSecret
camel.vault.azure.vaultName = vaultName
```

Or you can enable the usage of Azure Identity in the following way:

```
export $CAMEL_VAULT_AZURE_IDENTITY_ENABLED=true
export $CAMEL_VAULT_AZURE_VAULT_NAME=vaultName
```

You can also enable the usage of Azure Identity in the **application.properties** file such as:

```
camel.vault.azure.azureIdentityEnabled = true
camel.vault.azure.vaultName = vaultName
```

NOTE

camel.vault.azure configuration only applies to the Azure Key Vault properties function (E.g when resolving properties). When using the **operation** option to create, get, list secrets etc., you should provide the usual options for connecting to Azure Services.

At this point, you'll be able to reference a property in the following way:

```
<camelContext>
  <route>
    <from uri="direct:start"/>
```

```
<to uri="{{azure:route}}"/>
</route>
</camelContext>
```

Where route will be the name of the secret stored in the Azure Key Vault Service.

You could specify a default value in case the secret is not present on Azure Key Vault Service:

```
<camelContext>
  <route>
    <from uri="direct:start"/>
    <to uri="{{azure:route:default}}"/>
  </route>
</camelContext>
```

In this case, if the secret doesn't exist, the property will fall back to "default" as value.

Also, you are able to get a particular field of the secret, if you have, for example, a secret named database of this form:

```
{
  "username": "admin",
  "password": "password123",
  "engine": "postgres",
  "host": "127.0.0.1",
  "port": "3128",
  "dbname": "db"
}
```

You're able to do get single secret value in your route, like for example:

```
<camelContext>
  <route>
    <from uri="direct:start"/>
    <log message="Username is {{azure:database/username}}"/>
  </route>
</camelContext>
```

Or re-use the property as part of an endpoint.

You could specify a default value in case the particular field of secret is not present on Azure Key Vault:

```
<camelContext>
  <route>
    <from uri="direct:start"/>
    <log message="Username is {{azure:database/username:admin}}"/>
  </route>
</camelContext>
```

In this case, if the secret doesn't exist or the secret exists, but the username field is not part of the secret, the property will fall back to "admin" as value.

There is also the syntax to get a particular version of the secret for both the approach, with field/default value specified or only with secret:

■

```
<camelContext>
  <route>
    <from uri="direct:start"/>
    <to uri="{{azure:route@bf9b4f4b-8e63-43fd-a73c-3e2d3748b451}}"/>
  </route>
</camelContext>
```

This approach will return the RAW route secret with the version 'bf9b4f4b-8e63-43fd-a73c-3e2d3748b451'.

```
<camelContext>
  <route>
    <from uri="direct:start"/>
    <to uri="{{azure:route:default@bf9b4f4b-8e63-43fd-a73c-3e2d3748b451}}"/>
  </route>
</camelContext>
```

This approach will return the route secret value with version 'bf9b4f4b-8e63-43fd-a73c-3e2d3748b451' or default value in case the secret doesn't exist or the version doesn't exist.

```
<camelContext>
  <route>
    <from uri="direct:start"/>
    <log message="Username is {{azure:database/username:admin@bf9b4f4b-8e63-43fd-a73c-3e2d3748b451}}"/>
  </route>
</camelContext>
```

This approach will return the username field of the database secret with version 'bf9b4f4b-8e63-43fd-a73c-3e2d3748b451' or admin in case the secret doesn't exist or the version doesn't exist.

For the moment we are not considering the rotation function if any are applied, but it is in the work to be done.

The only requirement is adding the camel-azure-key-vault jar to your Camel application.

13.6.2. Automatic Camel context reloading on Secret Refresh

Being able to reload Camel context on a Secret Refresh could be done by specifying the usual credentials (the same used for Azure Key Vault Property Function).

With Environment variables:

```
export $CAMEL_VAULT_AZURE_TENANT_ID=tenantId
export $CAMEL_VAULT_AZURE_CLIENT_ID=clientId
export $CAMEL_VAULT_AZURE_CLIENT_SECRET=clientSecret
export $CAMEL_VAULT_AZURE_VAULT_NAME=vaultName
```

or as plain Camel main properties:

```
camel.vault.azure.tenantId = accessKey
camel.vault.azure.clientId = clientId
camel.vault.azure.clientSecret = clientSecret
camel.vault.azure.vaultName = vaultName
```

If you want to use Azure Identity with environment variables, you can do in the following way:

```
export $CAMEL_VAULT_AZURE_IDENTITY_ENABLED=true
export $CAMEL_VAULT_AZURE_VAULT_NAME=vaultName
```

You can also enable the usage of Azure Identity in the **application.properties** file such as:

```
camel.vault.azure.azureIdentityEnabled = true
camel.vault.azure.vaultName = vaultName
```

To enable the automatic refresh, you'll need additional properties to set:

```
camel.vault.azure.refreshEnabled=true
camel.vault.azure.refreshPeriod=60000
camel.vault.azure.secrets=Secret
camel.vault.azure.eventhubConnectionString=eventhub_conn_string
camel.vault.azure.blobAccountName=blob_account_name
camel.vault.azure.blobContainerName=blob_container_name
camel.vault.azure.blobAccessKey=blob_access_key
camel.main.context-reload-enabled = true
```

where **camel.vault.azure.refreshEnabled** will enable the automatic context reload, **camel.vault.azure.refreshPeriod** is the interval of time between two different checks for update events and **camel.vault.azure.secrets** is a regex representing the secrets we want to track for updates.

where **camel.vault.azure.eventhubConnectionString** is the eventhub connection string to get notification from, **camel.vault.azure.blobAccountName**, **camel.vault.azure.blobContainerName** and **camel.vault.azure.blobAccessKey** are the Azure Storage Blob parameters for the checkpoint store needed by Azure Eventhub.

Note that **camel.vault.azure.secrets** is not mandatory: if not specified the task responsible for checking updates events will take into accounts or the properties with an **azure:** prefix.

The only requirement is adding the camel-azure-key-vault jar to your Camel application.

13.6.3. Automatic Camel context reloading on Secret Refresh - Required Infrastructure's creation

First of all we need to create an application

```
az ad app create --display-name test-app-key-vault
```

Then we need to obtain credentials

```
az ad app credential reset --id <appld> --append --display-name 'Description: Key Vault app client' --end-date '2024-12-31'
```

This will return a result like this

```
{
  "appId": "appld",
  "password": "pwd",
```

```
"tenant": "tenantId"
}
```

You should take note of the password and use it as clientSecret parameter, together with the clientId and tenantId.

Now create the key vault

```
az keyvault create --name <vaultName> --resource-group <resourceGroup>
```

Create a service principal associated with the application Id

```
az ad sp create --id <appld>
```

At this point we need to add a role to the application with role assignment

```
az role assignment create --assignee <appld> --role "Key Vault Administrator" --scope
/subscriptions/<subscriptionId>/resourceGroups/<resourceGroup>/providers/Microsoft.KeyVault/vaults/<
vaultName>
```

Last step is to create policy on what can be or cannot be done with the application. In this case we just want to read the secret value. So This should be enough.

```
az keyvault set-policy --name <vaultName> --spn <appld> --secret-permissions get
```

You can create a secret through Azure CLI with the following command:

```
az keyvault secret set --name <secret_name> --vault-name <vaultName> -f <json-secret>
```

Now we need to setup the Eventhub/EventGrid notification for being informed about secrets updates.

First of all we'll need a Blob account and Blob container, to track Eventhub consuming activities.

```
az storage account create --name <blobAccountName> --resource-group <resourceGroup>
```

Then create a container

```
az storage container create --account-name <blobAccountName> --name <blobContainerName>
```

Then recover the access key for this purpose

```
az storage account keys list -g <resourceGroup> -n <blobAccountName>
```

Take note of the blob Account name, blob Container name and Blob Access Key to be used for setting up the vault.

Let's now create the Eventhub side

Create the namespace first

```
az eventhubs namespace create --resource-group <resourceGroup> --name <eventhub-namespace>
--location westus --sku Standard --enable-auto-inflate --maximum-throughput-units 20
```

Now create the resource

```
az eventhubs eventhub create --resource-group <resourceGroup> --namespace-name <eventhub-namespace> --name <eventhub-name> --cleanup-policy Delete --partition-count 15
```

In the Azure portal create a shared policy for the just created eventhub resource with "MANAGE" permissions and copy the connection string.

You now have all the required parameters to set up the vault.

13.7. MESSAGE HEADERS

The Azure Key Vault component supports 2 message header(s), which is/are listed below:

Name	Description	Default	Type
CamelAzureKeyVaultProducerOperation (producer) Constant: OPERATION	Overrides the desired operation to be used in the producer.		KeyVaultOperationDefinition
CamelAzureKeyVaultSecretName (producer) Constant: SECRET_NAME	The secret name to be used in Key Vault.		String

13.7.1. Azure Key Vault Producer operations

Azure Key Vault component provides the following operation on the producer side:

- createSecret
- getSecret
- deleteSecret
- purgeDeletedSecret

13.8. EXAMPLES

13.8.1. Producer Examples

- createSecret: this operation will create a secret in Azure Key Vault

```
from("direct:createSecret")
  .setHeader(KeyVaultConstants.SECRET_NAME, "Test")
  .setBody(constant("Test"))
  .to("azure-key-vault://test123?
clientId=RAW({{clientId}})&clientSecret=RAW({{clientSecret}})&tenantId=RAW({{tenantId}})")
```

- getSecret: this operation will get a secret from Azure Key Vault

```

from("direct:getSecret")
  .setHeader(KeyVaultConstants.SECRET_NAME, "Test")
  .to("azure-key-vault://test123?
clientId=RAW({{clientId}})&clientSecret=RAW({{clientSecret}})&tenantId=RAW({{tenantId}})&operation=
getSecret")

```

- `deleteSecret`: this operation will delete a Secret from Azure Key Vault

```

from("direct:deleteSecret")
  .setHeader(KeyVaultConstants.SECRET_NAME, "Test")
  .to("azure-key-vault://test123?
clientId=RAW({{clientId}})&clientSecret=RAW({{clientSecret}})&tenantId=RAW({{tenantId}})&operation=
deleteSecret")

```

- `purgeDeletedSecret`: this operation will purge a deleted Secret from Azure Key Vault

```

from("direct:purgeDeletedSecret")
  .setHeader(KeyVaultConstants.SECRET_NAME, "Test")
  .to("azure-key-vault://test123?
clientId=RAW({{clientId}})&clientSecret=RAW({{clientSecret}})&tenantId=RAW({{tenantId}})&operation=
purgeDeletedSecret")

```

13.9. SPRING BOOT AUTO-CONFIGURATION

The component supports 3 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.azure-key-vault.autowired-enabled</code>	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
<code>camel.component.azure-key-vault.enabled</code>	Whether to enable auto configuration of the azure-key-vault component. This is enabled by default.		Boolean
<code>camel.component.azure-key-vault.lazy-start-producer</code>	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 14. AZURE SERVICEBUS

Since Camel 3.12

Both producer and consumer are supported

The `azure-servicebus` component that integrates [Azure ServiceBus](#). Azure ServiceBus is a fully managed enterprise integration message broker. Service Bus can decouple applications and services. Service Bus offers a reliable and secure platform for asynchronous transfer of data and state. Data is transferred between different applications and services using messages.

Prerequisites

You must have a valid Windows Azure Storage account. More information is available at [Azure Documentation Portal](#).

14.1. DEPENDENCIES

When using **azure-servicebus** with Red Hat build of Camel Spring Boot, add the following Maven dependency to your **pom.xml** to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-azure-servicebus-starter</artifactId>
</dependency>
```

14.2. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

14.2.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).
- directly in the Java code.

14.2.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

14.3. COMPONENT OPTIONS

The Azure ServiceBus component supports 25 options, which are listed below.

Name	Description	Default	Type
amqpRetryOptions (common)	Sets the retry options for Service Bus clients. If not specified, the default retry options are used.		AmqpRetryOptions
amqpTransportType (common)	Sets the transport type by which all the communication with Azure Service Bus occurs. Default value is <code>AmqpTransportType#AMQP</code> . Enum values: • <code>Amqp</code> • <code>AmqpWebSockets</code>	AMQP	AmqpTransportType
clientOptions (common)	Sets the ClientOptions to be sent from the client built from this builder, enabling customization of certain properties, as well as support the addition of custom header information. Refer to the ClientOptions documentation for more information.		ClientOptions
configuration (common)	The component configurations.		ServiceBusConfiguration

Name	Description	Default	Type
proxyOptions (common)	Sets the proxy configuration to use for ServiceBusSenderAsyncClient. When a proxy is configured, AmqpTransportType#AMQP_WEB_SOCKETS must be used for the transport type.		ProxyOptions
serviceBusType (common)	Required The service bus type of connection to execute. Queue is for typical queue option and topic for subscription based model. Enum values: • queue • topic	queue	ServiceBusType
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
consumerOperation (consumer)	Sets the desired operation to be used in the consumer. Enum values: • receiveMessages • peekMessages	receiveMessages	ServiceBusConsumerOperationDefinition
disableAutoComplete (consumer)	Disables auto-complete and auto-abandon of received messages. By default, a successfully processed message is <code>\\link ServiceBusReceiverAsyncClient#complete(ServiceBusReceivedMessage) completed}</code> . If an error happens when the message is processed, it is <code>\\link ServiceBusReceiverAsyncClient#abandon(ServiceBusReceivedMessage) abandoned}</code> .	false	boolean

Name	Description	Default	Type
maxAutoLockRenewDuration (consumer)	Sets the amount of time to continue auto-renewing the lock. Setting Duration#ZERO or null disables auto-renewal. For <code>ServiceBusReceiveMode#RECEIVE_AND_DELETE</code> mode, auto-renewal is disabled.	5m	Duration
peekNumMaxMessages (consumer)	Set the max number of messages to be peeked during the peek operation.		Integer
prefetchCount (consumer)	Sets the prefetch count of the receiver. For both <code>ServiceBusReceiveMode#PEEK_LOCK</code> and <code>ServiceBusReceiveMode#RECEIVE_AND_DELETE</code> modes the default value is 1. Prefetch speeds up the message flow by aiming to have a message readily available for local retrieval when and before the application asks for one using <code>ServiceBusReceiverAsyncClient#receiveMessages()</code> . Setting a non-zero value will prefetch that number of messages. Setting the value to zero turns prefetch off.		int
receiverAsyncClient (consumer)	Autowired Sets the receiverAsyncClient in order to consume messages by the consumer.		ServiceBusReceiverAsyncClient
serviceBusReceiveMode (consumer)	Sets the receive mode for the receiver. Enum values: • PEEK_LOCK • RECEIVE_AND_DELETE	PEEK_LOCK	ServiceBusReceiveMode
subQueue (consumer)	Sets the type of the SubQueue to connect to. Enum values: • NONE • DEAD_LETTER_QUEUE • TRANSFER_DEAD_LETTER_QUEUE		SubQueue
subscriptionName (consumer)	Sets the name of the subscription in the topic to listen to. <code>topicOrQueueName</code> and <code>serviceBusType=topic</code> must also be set. This property is required if <code>serviceBusType=topic</code> and the consumer is in use.		String

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
producerOperation (producer)	Sets the desired operation to be used in the producer. Enum values: ● sendMessages ● scheduleMessages	sendMessage	ServiceBusProducerOperationDefinition
scheduledEnqueueTime (producer)	Sets OffsetDateTime at which the message should appear in the Service Bus queue or topic.		OffsetDateTime
senderAsyncClient (producer)	Autowired Sets SenderAsyncClient to be used in the producer.		ServiceBusSenderAsyncClient
serviceBusTransactionContext (producer)	Represents transaction in service. This object just contains transaction id.		ServiceBusTransactionContext
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
connectionString (security)	Sets the connection string for a Service Bus namespace or a specific Service Bus resource.		String
fullyQualifiedNamespace (security)	Fully Qualified Namespace of the service bus.		String
tokenCredential (security)	A TokenCredential for Azure AD authentication, implemented in com.azure.identity.		TokenCredential

14.4. ENDPOINT OPTIONS

The Azure ServiceBus endpoint is configured using URI syntax:

```
azure-servicebus:topicOrQueueName
```

with the following path and query parameters:

14.4.1. Path Parameters (1 parameters)

Name	Description	Default	Type
topicOrQueueName (common)	Selected topic name or the queue name, that is depending on serviceBusType config. For example if serviceBusType=queue, then this will be the queue name and if serviceBusType=topic, this will be the topic name.		String

14.4.2. Query Parameters (25 parameters)

Name	Description	Default	Type
amqpRetryOptions (common)	Sets the retry options for Service Bus clients. If not specified, the default retry options are used.		AmqpRetryOptions
amqpTransportType (common)	Sets the transport type by which all the communication with Azure Service Bus occurs. Default value is AmqpTransportType#AMQP. Enum values: • Amqp • AmqpWebSockets	AMQP	AmqpTransportType
clientOptions (common)	Sets the ClientOptions to be sent from the client built from this builder, enabling customization of certain properties, as well as support the addition of custom header information. Refer to the ClientOptions documentation for more information.		ClientOptions
proxyOptions (common)	Sets the proxy configuration to use for ServiceBusSenderAsyncClient. When a proxy is configured, AmqpTransportType#AMQP_WEB_SOCKETS must be used for the transport type.		ProxyOptions

Name	Description	Default	Type
serviceBusType (common)	Required The service bus type of connection to execute. Queue is for typical queue option and topic for subscription based model. Enum values: • queue • topic	queue	ServiceBusType
consumerOperation (consumer)	Sets the desired operation to be used in the consumer. Enum values: • receiveMessages • peekMessages	receiveMessages	ServiceBusConsumerOperationDefinition
disableAutoComplete (consumer)	Disables auto-complete and auto-abandon of received messages. By default, a successfully processed message is <code>ServiceBusReceiverAsyncClient#complete(ServiceBusReceivedMessage) completed</code>. If an error happens when the message is processed, it is <code>ServiceBusReceiverAsyncClient#abandon(ServiceBusReceivedMessage) abandoned</code>.	false	boolean
maxAutoLockRenewDuration (consumer)	Sets the amount of time to continue auto-renewing the lock. Setting <code>Duration#ZERO</code> or null disables auto-renewal. For <code>ServiceBusReceiveMode#RECEIVE_AND_DELETE</code> mode, auto-renewal is disabled.	5m	Duration
peekNumMaxMessages (consumer)	Set the max number of messages to be peeked during the peek operation.		Integer

Name	Description	Default	Type
prefetchCount (consumer)	Sets the prefetch count of the receiver. For both <code>{link ServiceBusReceiveMode#PEEK_LOCK PEEK_LOCK}</code> and <code>{link ServiceBusReceiveMode#RECEIVE_AND_DELETE RECEIVE_AND_DELETE}</code> modes the default value is 1. Prefetch speeds up the message flow by aiming to have a message readily available for local retrieval when and before the application asks for one using <code>ServiceBusReceiverAsyncClient#receiveMessages()</code> . Setting a non-zero value will prefetch that number of messages. Setting the value to zero turns prefetch off.		int
receiverAsyncClient (consumer)	Autowired Sets the receiverAsyncClient in order to consume messages by the consumer.		ServiceBusReceiverAsyncClient
serviceBusReceiveMode (consumer)	Sets the receive mode for the receiver. Enum values: ● PEEK_LOCK ● RECEIVE_AND_DELETE	PEEK_LOCK	ServiceBusReceiveMode
subQueue (consumer)	Sets the type of the SubQueue to connect to. Enum values: ● NONE ● DEAD_LETTER_QUEUE ● TRANSFER_DEAD_LETTER_QUEUE		SubQueue
subscriptionName (consumer)	Sets the name of the subscription in the topic to listen to. <code>topicOrQueueName</code> and <code>serviceBusType=topic</code> must also be set. This property is required if <code>serviceBusType=topic</code> and the consumer is in use.		String
bridgeErrorHandler (consumer (advanced))	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean

Name	Description	Default	Type
exceptionHandler (consumer (advanced))	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at <code>WARN</code> or <code>ERROR</code> level and ignored.		<code>ExceptionHandler</code>
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • <code>InOnly</code> • <code>InOut</code> • <code>InOptionalOut</code>		<code>ExchangePattern</code>
producerOperation (producer)	Sets the desired operation to be used in the producer. Enum values: • <code>sendMessages</code> • <code>scheduleMessages</code>	<code>sendMessage</code> s	<code>ServiceBusProducerOperationDefinition</code>
scheduledEnqueueTime (producer)	Sets <code>OffsetDateTime</code> at which the message should appear in the Service Bus queue or topic.		<code>OffsetDateTime</code>
senderAsyncClient (producer)	Autowired Sets <code>SenderAsyncClient</code> to be used in the producer.		<code>ServiceBusSenderAsyncClient</code>
serviceBusTransactionContext (producer)	Represents transaction in service. This object just contains transaction id.		<code>ServiceBusTransactionContext</code>
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow <code>CamelContext</code> and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	<code>false</code>	<code>boolean</code>
connectionString (security)	Sets the connection string for a Service Bus namespace or a specific Service Bus resource.		<code>String</code>

Name	Description	Default	Type
fullyQualifiedNamespace (security)	Fully Qualified Namespace of the service bus.		String
tokenCredential (security)	A TokenCredential for Azure AD authentication, implemented in com.azure.identity.		TokenCredential

14.5. ASYNC CONSUMER AND PRODUCER

This component implements the async Consumer and producer. This allows camel route to consume and produce events asynchronously without blocking any threads.

14.6. MESSAGE HEADERS

The Azure ServiceBus component supports 25 message header(s), which is/are listed below:

Name	Description	Default	Type
CamelAzureServiceBusApplicationProperties (common) Constant: APPLICATION_PROPERTIES	The application properties (also known as custom properties) on messages sent and received by the producer and consumer, respectively.		Map
CamelAzureServiceBusContentType (consumer) Constant: CONTENT_TYPE	Gets the content type of the message.		String
CamelAzureServiceBusCorrelationId (consumer) Constant: CORRELATION_ID	Gets a correlation identifier.		String

Name	Description	Default	Type
CamelAzureServiceBusDeadLetterErrorDescription (consumer) Constant: DEAD_LETTER_ERROR_DESCRIPTION	Gets the description for a message that has been dead-lettered.		String
CamelAzureServiceBusDeadLetterReason (consumer) Constant: DEAD_LETTER_REASON	Gets the reason a message was dead-lettered.		String
CamelAzureServiceBusDeadLetterSource (consumer) Constant: DEAD_LETTER_SOURCE	Gets the name of the queue or subscription that this message was enqueued on, before it was dead-lettered.		String
CamelAzureServiceBusDeliveryCount (consumer) Constant: DELIVERY_COUNT	Gets the number of the times this message was delivered to clients.		long
CamelAzureServiceBusEnqueuedSequenceNumber (consumer) Constant: ENQUEUED_SEQUENCE_NUMBER	Gets the enqueued sequence number assigned to a message by Service Bus.		long

Name	Description	Default	Type
CamelAzureServiceBusEnqueuedTime (consumer) Constant: ENQUEUED_TIME	Gets the datetime at which this message was enqueued in Azure Service Bus.		OffsetDateTime
CamelAzureServiceBusExpiresAt (consumer) Constant: EXPIRES_AT	Gets the datetime at which this message will expire.		OffsetDateTime
CamelAzureServiceBusLockToken (consumer) Constant: LOCK_TOKEN	Gets the lock token for the current message.		String
CamelAzureServiceBusLockedUntil (consumer) Constant: LOCKED_UNTIL	Gets the datetime at which the lock of this message expires.		OffsetDateTime
CamelAzureServiceBusMessageId (consumer) Constant: MESSAGE_ID	Gets the identifier for the message.		String
CamelAzureServiceBusPartitionKey (consumer) Constant: PARTITION_KEY	Gets the partition key for sending a message to a partitioned entity.		String
CamelAzureServiceBusRawAmqpMessage (consumer) Constant: RAW_AMQP_MESSAGE	The representation of message as defined by AMQP protocol.		AmqpAnnotatedMessage

Name	Description	Default	Type
CamelAzureServiceBusReplyTo (consumer) Constant: REPLY_TO	Gets the address of an entity to send replies to.		String
CamelAzureServiceBusReplyToSessionId (consumer) Constant: REPLY_TO_SESSION_ID	Gets or sets a session identifier augmenting the ReplyTo address.		String
CamelAzureServiceBusSequenceNumber (consumer) Constant: SEQUENCE_NUMBER	Gets the unique number assigned to a message by Service Bus.		long
CamelAzureServiceBusSessionId (consumer) Constant: SESSION_ID	Gets the session id of the message.		String
CamelAzureServiceBusSubject (consumer) Constant: SUBJECT	Gets the subject for the message.		String
CamelAzureServiceBusTimeToLive (consumer) Constant: TIME_TO_LIVE	Gets the duration before this message expires.		Duration
CamelAzureServiceBusTo (consumer) Constant: TO	Gets the to address.		String

Name	Description	Default	Type
CamelAzureServiceBusScheduledEnqueueTime (common) Constant: SCHEDULED_ENQUEUE_TIME	(producer) Overrides the OffsetDateTime at which the message should appear in the Service Bus queue or topic. (consumer) Gets the scheduled enqueue time of this message.		OffsetDateTime
CamelAzureServiceBusServiceBusTransactionContext (producer) Constant: SERVICE_BUS_TRANSACTION_CONTEXT	Overrides the transaction in service. This object just contains transaction id.		ServiceBusTransactionContext
CamelAzureServiceBusProducerOperation (producer) Constant: PRODUCER_OPERATION	Overrides the desired operation to be used in the producer. Enum values: • <code>sendMessages</code> • <code>scheduleMessages</code>		ServiceBusProducerOperationDefinition

14.6.1. Message Body

In the producer, this component accepts message body of **String** type or **List<String>** to send batch messages.

In the consumer, the returned message body will be of type `String`.

14.6.2. Azure ServiceBus Producer operations

Operation	Description
sendMessages	Sends a set of messages to a Service Bus queue or topic using a batched approach.
scheduleMessages	Sends a scheduled message to the Azure Service Bus entity this sender is connected to. A scheduled message is enqueued and made available to receivers only at the scheduled enqueue time.

14.6.3. Azure ServiceBus Consumer operations

Operation	Description
receiveMessages	Receives an infinite stream of messages from the Service Bus entity.
peekMessages	Reads the next batch of active messages without changing the state of the receiver or the message source.

14.6.3.1. Examples

- **sendMessages**

```
from("direct:start")
  .process(exchange -> {
    final List<Object> inputBatch = new LinkedList<>();
    inputBatch.add("test batch 1");
    inputBatch.add("test batch 2");
    inputBatch.add("test batch 3");
    inputBatch.add(123456);

    exchange.getIn().setBody(inputBatch);
  })
  .to("azure-servicebus:test/?connectionString=test")
  .to("mock:result");
```

- **scheduleMessages**

```
from("direct:start")
  .process(exchange -> {
    final List<Object> inputBatch = new LinkedList<>();
    inputBatch.add("test batch 1");
    inputBatch.add("test batch 2");
    inputBatch.add("test batch 3");
    inputBatch.add(123456);

    exchange.getIn().setHeader(ServiceBusConstants.SCHEDULED_ENQUEUE_TIME,
      OffsetDateTime.now());
    exchange.getIn().setBody(inputBatch);
  })
  .to("azure-servicebus:test/?connectionString=test&producerOperation=scheduleMessages")
  .to("mock:result");
```

- **receiveMessages**

```
from("azure-servicebus:test/?connectionString=test")
  .log("${body}")
  .to("mock:result");
```

- `peekMessages`

```
from("azure-servicebus:test//?
connectionString=test&consumerOperation=peekMessages&peekNumMaxMessages=3")
.log("${body}")
.to("mock:result");
```

14.7. SPRING BOOT AUTO-CONFIGURATION

The component supports 26 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.azure-servicebus.amqp-retry-options</code>	Sets the retry options for Service Bus clients. If not specified, the default retry options are used. The option is a <code>com.azure.core.amqp.AmqpRetryOptions</code> type.		<code>AmqpRetryOptions</code>
<code>camel.component.azure-servicebus.amqp-transport-type</code>	Sets the transport type by which all the communication with Azure Service Bus occurs. Default value is <code>AmqpTransportType#AMQP</code> .		<code>AmqpTransportType</code>
<code>camel.component.azure-servicebus.autowired-enabled</code>	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	<code>true</code>	<code>Boolean</code>
<code>camel.component.azure-servicebus.bridge-error-handler</code>	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	<code>false</code>	<code>Boolean</code>
<code>camel.component.azure-servicebus.client-options</code>	Sets the <code>ClientOptions</code> to be sent from the client built from this builder, enabling customization of certain properties, as well as support the addition of custom header information. Refer to the <code>ClientOptions</code> documentation for more information. The option is a <code>com.azure.core.util.ClientOptions</code> type.		<code>ClientOptions</code>

Name	Description	Default	Type
<code>camel.component.azure-servicebus.configuration</code>	The component configurations. The option is a <code>org.apache.camel.component.azure.servicebus.ServiceBusConfiguration</code> type.		<code>ServiceBusConfiguration</code>
<code>camel.component.azure-servicebus.connection-string</code>	Sets the connection string for a Service Bus namespace or a specific Service Bus resource.		<code>String</code>
<code>camel.component.azure-servicebus.consumer-operation</code>	Sets the desired operation to be used in the consumer.		<code>ServiceBusConsumerOperationDefinition</code>
<code>camel.component.azure-servicebus.disable-auto-complete</code>	Disables auto-complete and auto-abandon of received messages. By default, a successfully processed message is <code>\\link ServiceBusReceiverAsyncClient#complete(ServiceBusReceivedMessage) completed</code> . If an error happens when the message is processed, it is <code>\\link ServiceBusReceiverAsyncClient#abandon(ServiceBusReceivedMessage) abandoned</code> .	<code>false</code>	<code>Boolean</code>
<code>camel.component.azure-servicebus.enabled</code>	Whether to enable auto configuration of the azure-servicebus component. This is enabled by default.		<code>Boolean</code>
<code>camel.component.azure-servicebus.fully-qualified-namespace</code>	Fully Qualified Namespace of the service bus.		<code>String</code>
<code>camel.component.azure-servicebus.lazy-start-producer</code>	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow <code>CamelContext</code> and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	<code>false</code>	<code>Boolean</code>

Name	Description	Default	Type
camel.component.azure-servicebus.max-auto-lock-renew-duration	Sets the amount of time to continue auto-renewing the lock. Setting Duration#ZERO or null disables auto-renewal. For <code>ServiceBusReceiveMode#RECEIVE_AND_DELETE</code> mode, auto-renewal is disabled. The option is a <code>java.time.Duration</code> type.		Duration
camel.component.azure-servicebus.peek-num-max-messages	Set the max number of messages to be peeked during the peek operation.		Integer
camel.component.azure-servicebus.prefetch-count	Sets the prefetch count of the receiver. For both <code>ServiceBusReceiveMode#PEEK_LOCK</code> and <code>ServiceBusReceiveMode#RECEIVE_AND_DELETE</code> modes the default value is 1. Prefetch speeds up the message flow by aiming to have a message readily available for local retrieval when and before the application asks for one using <code>ServiceBusReceiverAsyncClient#receiveMessages()</code> . Setting a non-zero value will prefetch that number of messages. Setting the value to zero turns prefetch off.		Integer
camel.component.azure-servicebus.producer-operation	Sets the desired operation to be used in the producer.		ServiceBusProducerOperationDefinition
camel.component.azure-servicebus.proxy-options	Sets the proxy configuration to use for <code>ServiceBusSenderAsyncClient</code> . When a proxy is configured, <code>AmqpTransportType#AMQP_WEB_SOCKETS</code> must be used for the transport type. The option is a <code>com.azure.core.amqp.ProxyOptions</code> type.		ProxyOptions
camel.component.azure-servicebus.receiver-async-client	Sets the <code>receiverAsyncClient</code> in order to consume messages by the consumer. The option is a <code>com.azure.messaging.servicebus.ServiceBusReceiverAsyncClient</code> type.		ServiceBusReceiverAsyncClient
camel.component.azure-servicebus.scheduled-enqueue-time	Sets <code>OffsetDateTime</code> at which the message should appear in the Service Bus queue or topic. The option is a <code>java.time.OffsetDateTime</code> type.		OffsetDateTime

Name	Description	Default	Type
camel.component.azure-servicebus.sender-async-client	Sets SenderAsyncClient to be used in the producer. The option is a com.azure.messaging.servicebus.ServiceBusSenderAsyncClient type.		ServiceBusSenderAsyncClient
camel.component.azure-servicebus.service-bus-receive-mode	Sets the receive mode for the receiver.		ServiceBusReceiveMode
camel.component.azure-servicebus.service-bus-transaction-context	Represents transaction in service. This object just contains transaction id. The option is a com.azure.messaging.servicebus.ServiceBusTransactionContext type.		ServiceBusTransactionContext
camel.component.azure-servicebus.service-bus-type	The service bus type of connection to execute. Queue is for typical queue option and topic for subscription based model.		ServiceBusType
camel.component.azure-servicebus.sub-queue	Sets the type of the SubQueue to connect to.		SubQueue
camel.component.azure-servicebus.subscription-name	Sets the name of the subscription in the topic to listen to. topicOrQueueName and serviceBusType=topic must also be set. This property is required if serviceBusType=topic and the consumer is in use.		String
camel.component.azure-servicebus.token-credential	A TokenCredential for Azure AD authentication, implemented in com.azure.identity. The option is a com.azure.core.credential.TokenCredential type.		TokenCredential

CHAPTER 15. AZURE STORAGE BLOB SERVICE

Both producer and consumer are supported

The Azure Storage Blob component is used for storing and retrieving blobs from [Azure Storage Blob Service](#) using **Azure APIs v12**. However in case of versions above v12, we will see if this component can adopt these changes depending on how much breaking changes can result.

Prerequisites

You must have a valid Windows Azure Storage account. More information is available at [Azure Documentation Portal](#).

15.1. DEPENDENCIES

When using **azure-storage-blob** with Red Hat build of Camel Spring Boot, add the following Maven dependency to your **pom.xml** to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-azure-storage-blob-starter</artifactId>
</dependency>
```

15.2. URI FORMAT

```
azure-storage-blob://accountName[/containerName][?options]
```

In case of consumer, **accountName**, **containerName** are required. In case of producer, it depends on the operation that is being requested, for example if operation is on a container level, for example, **createContainer**, **accountName** and **containerName** are only required, but in case of operation being requested in blob level, for example, **getBlob**, **accountName**, **containerName** and **blobName** are required.

The blob will be created if it does not already exist. You can append query options to the URI in the following format,

?options=value&option2=value&...

15.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

15.3.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a

few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).
- directly in the Java code.

15.3.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

15.4. COMPONENT OPTIONS

The Azure Storage Blob Service component supports 35 options, which are listed below.

Name	Description	Default	Type
blobName (common)	The blob name, to consume specific blob from a container. However on producer, is only required for the operations on the blob level.		String
blobOffset (common)	Set the blob offset for the upload or download operations, default is 0.	0	long

Name	Description	Default	Type
blobType (common)	The blob type in order to initiate the appropriate settings for each blob type. Enum values: • blockblob • appendblob • pageblob	blockblob	BlobType
closeStreamAfterRead (common)	Close the stream after read or keep it open, default is true.	true	boolean
configuration (common)	The component configurations.		BlobConfiguration
credentials (common)	StorageSharedKeyCredential can be injected to create the azure client, this holds the important authentication information.		StorageSharedKeyCredential
credentialType (common)	Determines the credential strategy to adopt. Enum values: • SHARED_ACCOUNT_KEY • SHARED_KEY_CREDENTIAL • AZURE_IDENTITY • AZURE_SAS	AZURE_IDENTITY	CredentialType
dataCount (common)	How many bytes to include in the range. Must be greater than or equal to 0 if specified.		Long
fileDir (common)	The file directory where the downloaded blobs will be saved to, this can be used in both, producer and consumer.		String
maxResultsPerPage (common)	Specifies the maximum number of blobs to return, including all BlobPrefix elements. If the request does not specify maxResultsPerPage or specifies a value greater than 5,000, the server will return up to 5,000 items.		Integer

Name	Description	Default	Type
maxRetryRequests (common)	Specifies the maximum number of additional HTTP Get requests that will be made while reading the data from a response body.	0	int
prefix (common)	Filters the results to return only blobs whose names begin with the specified prefix. May be null to return all blobs.		String
regex (common)	Filters the results to return only blobs whose names match the specified regular expression. May be null to return all if both prefix and regex are set, regex takes the priority and prefix is ignored.		String
sasToken (common)	Set a SAS Token in case of usage of Shared Access Signature		String
serviceClient (common)	Autowired Client to a storage account. This client does not hold any state about a particular storage account but is instead a convenient way of sending off appropriate requests to the resource on the service. It may also be used to construct URLs to blobs and containers. This client contains operations on a service account. Operations on a container are available on BlobContainerClient through <code>BlobServiceClient#getBlobContainerClient(String)</code> , and operations on a blob are available on BlobClient through <code>BlobContainerClient#getBlobClient(String)</code> .		BlobServiceClient
timeout (common)	An optional timeout value beyond which a RuntimeException will be raised.		Duration
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
blobSequenceNumber (producer)	A user-controlled value that you can use to track requests. The value of the sequence number must be between 0 and 263 - 1. The default value is 0.	0	Long

Name	Description	Default	Type
blockListType (producer)	Specifies which type of blocks to return. Enum values: ● committed ● uncommitted ● all	COMMITTED	BlockListType
changeFeedContext (producer)	When using getChangeFeed producer operation, this gives additional context that is passed through the Http pipeline during the service call.		Context
changeFeedEndTime (producer)	When using getChangeFeed producer operation, this filters the results to return events approximately before the end time. Note: A few events belonging to the next hour can also be returned. A few events belonging to this hour can be missing; to ensure all events from the hour are returned, round the end time up by an hour.		OffsetDateTime
changeFeedStartTime (producer)	When using getChangeFeed producer operation, this filters the results to return events approximately after the start time. Note: A few events belonging to the previous hour can also be returned. A few events belonging to this hour can be missing; to ensure all events from the hour are returned, round the start time down by an hour.		OffsetDateTime
closeStreamAfterWrite (producer)	Close the stream after write or keep it open, default is true.	true	boolean
commitBlockListLater (producer)	When is set to true, the staged blocks will not be committed directly.	true	boolean
createAppendBlob (producer)	When is set to true, the append blocks will be created when committing append blocks.	true	boolean
createPageBlob (producer)	When is set to true, the page blob will be created when uploading page blob.	true	boolean
downloadLinkExpiration (producer)	Override the default expiration (millis) of URL download link.		Long

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
operation (producer)	The blob operation that can be used with this component on the producer. Enum values: ● listBlobContainers ● createBlobContainer ● deleteBlobContainer ● listBlobs ● getBlob ● deleteBlob ● downloadBlobToFile ● downloadLink ● uploadBlockBlob ● stageBlockBlobList ● commitBlobBlockList ● getBlobBlockList ● createAppendBlob ● commitAppendBlob ● createPageBlob ● uploadPageBlob ● resizePageBlob ● clearPageBlob ● getPageBlobRanges	listBlobContainers	BlobOperationsDefinition

Name	Description	Default	Type
pageBlobSize (producer)	Specifies the maximum size for the page blob, up to 8 TB. The page blob size must be aligned to a 512-byte boundary.	512	Long
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
healthCheckConsumerEnabled (health)	Used for enabling or disabling all consumer based health checks from this component.	true	boolean
healthCheckProducerEnabled (health)	Used for enabling or disabling all producer based health checks from this component. Notice: Camel has by default disabled all producer based health-checks. You can turn on producer checks globally by setting camel.health.producersEnabled=true.	true	boolean
accessKey (security)	Access key for the associated azure account name to be used for authentication with azure blob services.		String
sourceBlobAccessKey (security)	Source Blob Access Key: for copyblob operation, sadly, we need to have an accessKey for the source blob we want to copy Passing an accessKey as header, it's unsafe so we could set as key.		String

15.5. ENDPOINT OPTIONS

The Azure Storage Blob Service endpoint is configured using URI syntax:

```
azure-storage-blob:accountName/containerName
```

with the following path and query parameters:

15.5.1. Path Parameters (2 parameters)

Name	Description	Default	Type
accountName (common)	Azure account name to be used for authentication with azure blob services.		String

Name	Description	Default	Type
containerName (common)	The blob container name.		String

15.5.2. Query Parameters (50 parameters)

Name	Description	Default	Type
blobName (common)	The blob name, to consume specific blob from a container. However on producer, is only required for the operations on the blob level.		String
blobOffset (common)	Set the blob offset for the upload or download operations, default is 0.	0	long
blobServiceClient (common)	Client to a storage account. This client does not hold any state about a particular storage account but is instead a convenient way of sending off appropriate requests to the resource on the service. It may also be used to construct URLs to blobs and containers. This client contains operations on a service account. Operations on a container are available on BlobContainerClient through <code>getBlobContainerClient(String)</code> , and operations on a blob are available on BlobClient through <code>getBlobContainerClient(String).getBlobClient(String)</code> .		BlobServiceClient
blobType (common)	The blob type in order to initiate the appropriate settings for each blob type. Enum values: • blockblob • appendblob • pageblob	blockblob	BlobType
closeStreamAfterRead (common)	Close the stream after read or keep it open, default is true.	true	boolean
credentials (common)	StorageSharedKeyCredential can be injected to create the azure client, this holds the important authentication information.		StorageSharedKeyCredential

Name	Description	Default	Type
credentialType (common)	Determines the credential strategy to adopt. Enum values: • SHARED_ACCOUNT_KEY • SHARED_KEY_CREDENTIAL • AZURE_IDENTITY • AZURE_SAS	AZURE_IDENTITY	CredentialType
dataCount (common)	How many bytes to include in the range. Must be greater than or equal to 0 if specified.		Long
fileDir (common)	The file directory where the downloaded blobs will be saved to, this can be used in both, producer and consumer.		String
maxResultsPerPage (common)	Specifies the maximum number of blobs to return, including all BlobPrefix elements. If the request does not specify maxResultsPerPage or specifies a value greater than 5,000, the server will return up to 5,000 items.		Integer
maxRetryRequests (common)	Specifies the maximum number of additional HTTP Get requests that will be made while reading the data from a response body.	0	int
prefix (common)	Filters the results to return only blobs whose names begin with the specified prefix. May be null to return all blobs.		String
regex (common)	Filters the results to return only blobs whose names match the specified regular expression. May be null to return all if both prefix and regex are set, regex takes the priority and prefix is ignored.		String
sasToken (common)	Set a SAS Token in case of usage of Shared Access Signature.		String

Name	Description	Default	Type
serviceClient (common)	Autowired Client to a storage account. This client does not hold any state about a particular storage account but is instead a convenient way of sending off appropriate requests to the resource on the service. It may also be used to construct URLs to blobs and containers. This client contains operations on a service account. Operations on a container are available on BlobContainerClient through BlobServiceClient#getBlobContainerClient(String), and operations on a blob are available on BlobClient through BlobContainerClient#getBlobClient(String).		BlobServiceClient
timeout (common)	An optional timeout value beyond which a RuntimeException will be raised.		Duration
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: ● InOnly ● InOut ● InOptionalOut		ExchangePattern

Name	Description	Default	Type
pollStrategy (consumer (advanced))	A pluggable <code>org.apache.camel.PollingConsumerPollingStrategy</code> allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		<code>PollingConsumerPollStrategy</code>
blobSequenceNumber (producer)	A user-controlled value that you can use to track requests. The value of the sequence number must be between 0 and 263 - 1. The default value is 0.	0	Long
blockListType (producer)	Specifies which type of blocks to return. Enum values: ● committed ● uncommitted ● all	COMMITTED	BlockListType
changeFeedContext (producer)	When using <code>getChangeFeed</code> producer operation, this gives additional context that is passed through the Http pipeline during the service call.		Context
changeFeedEndTime (producer)	When using <code>getChangeFeed</code> producer operation, this filters the results to return events approximately before the end time. Note: A few events belonging to the next hour can also be returned. A few events belonging to this hour can be missing; to ensure all events from the hour are returned, round the end time up by an hour.		OffsetDateTime
changeFeedStartTime (producer)	When using <code>getChangeFeed</code> producer operation, this filters the results to return events approximately after the start time. Note: A few events belonging to the previous hour can also be returned. A few events belonging to this hour can be missing; to ensure all events from the hour are returned, round the start time down by an hour.		OffsetDateTime
closeStreamAfterWrite (producer)	Close the stream after write or keep it open, default is true.	true	boolean
commitBlockListLater (producer)	When is set to true, the staged blocks will not be committed directly.	true	boolean

Name	Description	Default	Type
createAppendBlob (producer)	When is set to true, the append blocks will be created when committing append blocks.	true	boolean
createPageBlob (producer)	When is set to true, the page blob will be created when uploading page blob.	true	boolean
downloadLinkExpiration (producer)	Override the default expiration (millis) of URL download link.		Long
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

Name	Description	Default	Type
operation (producer)	The blob operation that can be used with this component on the producer. Enum values: • listBlobContainers • createBlobContainer • deleteBlobContainer • listBlobs • getBlob • deleteBlob • downloadBlobToFile • downloadLink • uploadBlockBlob • stageBlockBlobList • commitBlobBlockList • getBlobBlockList • createAppendBlob • commitAppendBlob • createPageBlob • uploadPageBlob • resizePageBlob • clearPageBlob • getPageBlobRanges	listBlobContainers	BlobOperationsDefinition
pageBlobSize (producer)	Specifies the maximum size for the page blob, up to 8 TB. The page blob size must be aligned to a 512-byte boundary.	512	Long
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.		int

Name	Description	Default	Type
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then <code>backoffIdleThreshold</code> and/or <code>backoffErrorThreshold</code> must also be configured.		int
delay (scheduler)	Milliseconds before the next poll.	500	long
greedy (scheduler)	If greedy is enabled, then the <code>ScheduledPollConsumer</code> will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts.	1000	long
repeatCount (scheduler)	Specifies a maximum limit of number of fires. So if you set it to 1, the scheduler will only fire once. If you set it to 5, it will only fire five times. A value of zero or negative means fire forever.	0	long
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that. Enum values: ● TRACE ● DEBUG ● INFO ● WARN ● ERROR ● OFF	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz component. Use value spring or quartz for built in scheduler.	none	Object

Name	Description	Default	Type
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for initialDelay and delay options. Enum values: • NANOSECONDS • MICROSECONDS • MILLISECONDS • SECONDS • MINUTES • HOURS • DAYS	MILLISECONDS	TimeUnit
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.	true	boolean
accessKey (security)	Access key for the associated azure account name to be used for authentication with azure blob services.		String
sourceBlobAccessKey (security)	Source Blob Access Key: for copyblob operation, sadly, we need to have an accessKey for the source blob we want to copy Passing an accessKey as header, it's unsafe so we could set as key.		String

Required information options

To use this component, you have 3 options in order to provide the required Azure authentication information:

- Provide a link: [BlobServiceClient](#) instance which can be injected into blobServiceClient. Note: No need to create a specific client, for Examples: **BlockBlobClient**, the **BlobServiceClient** represents the upper level which can be used to retrieve lower level clients.
- Provide an Azure Identity, when specifying **credentialType=AZURE_IDENTITY** and providing required [environment variables](#). This enables service principal (for example, app registration) authentication with secret/certificate as well as username password. Note that this is the default authentication strategy.
- Provide a shared storage account key, when specifying

credentialType=SHARED_ACCOUNT_KEY and providing **accountName** and **accessKey** for your Azure account, this is the simplest way to get started. The **accessKey** can be generated through your Azure portal.

- Provide a shared storage account key, when specifying **credentialType=SHARED_KEY_CREDENTIAL** and providing a [StorageSharedKeyCredential](#) instance which can be injected into credentials option.
- Via Azure SAS, when specifying **credentialType=AZURE_SAS** and providing a SAS Token parameter through the `sasToken` parameter.

15.6. USAGE

For example, in order to download a blob content from the blob **hello.txt** located on the **container1** in the **camelazure** storage account, use the following snippet:

```
from("azure-storage-blob://camelazure/container1?
blobName=hello.txt&credentialType=SHARED_ACCOUNT_KEY&accessKey=RAW(yourAccessKey)"
).to("file://blobdirectory");
```

15.6.1. Message headers

The Azure Storage Blob Service component supports 63 message header(s), which is/are listed below:

Header	Variable Name	Type	Operations	Description
CamelAzureStorageBlobTimeout	BlobConstants.TIMEOUT	Duration	All	An optional timeout value beyond which a {@link RuntimeException} will be raised.
CamelAzureStorageBlobMetadata	BlobConstants.METADATA	Map<String,String>	Operations related to container and blob	Metadata to associate with the container or blob.
CamelAzureStorageBlobPublicAccessType	BlobConstants.PUBLIC_ACCESS_TYPE	PublicAccessType	createContainer	Specifies how the data in this container is available to the public. Pass null for no public access.

Header	Variable Name	Type	Operations	Description
CamelAzureStorageBlobRequestCondition	BlobConstants.BLOB_REQUEST_CONDITION	BlobRequestConditions	Operations related to container and blob	This contains values which will restrict the successful operation of a variety of requests to the conditions present. These conditions are entirely optional.
CamelAzureStorageBlobListDetails	BlobConstants.BLOB_LIST_DETAILS	BlobListDetails	listBlobs	The details for listing specific blobs
CamelAzureStorageBlobPrefix	BlobConstants.PREFIX	String	listBlobs, getBlob	Filters the results to return only blobs whose names begin with the specified prefix. May be null to return all blobs.
CamelAzureStorageBlobMaxResultsPerPage	BlobConstants.MAX_RESULTS_PER_PAGE	Integer	listBlobs	Specifies the maximum number of blobs to return, including all BlobPrefix elements. If the request does not specify <code>maxResultsPerPage</code> or specifies a value greater than 5,000, the server will return up to 5,000 items.
CamelAzureStorageBlobListBlobOptions	BlobConstants.LIST_BLOB_OPTIONS	ListBlobsOptions	listBlobs	Defines options available to configure the behavior of a call to <code>listBlobsFlatSegment</code> on a <code>{@link BlobContainerClient}</code> object.

Header	Variable Name	Type	Operations	Description
CamelAzureStorageBlobHttpHeaders	BlobConstants.BLOB_HTTP_HEADERS	BlobHttpHeaders	uploadBlockBlob, commitBlockBlobList, createAppendBlob, createPageBlob	Additional parameters for a set of operations.
CamelAzureStorageBlobAccessTier	BlobConstants.ACCESS_TIER	AccessTier	uploadBlockBlob, commitBlockBlobList	Defines values for AccessTier.
CamelAzureStorageBlobContentMD5	BlobConstants.CONTENT_MD5	byte[]	Most operations related to upload blob	An MD5 hash of the block content. This hash is used to verify the integrity of the block during transport. When this header is specified, the storage service compares the hash of the content that has arrived with this header value. Note that this MD5 hash is not stored with the blob. If the two hashes do not match, the operation will fail.
CamelAzureStorageBlobPageBlobRange	BlobConstants.PAGE_BLOB_RANGE	PageRange	Operations related to page blob	A {@link PageRange} object. Given that pages must be aligned with 512-byte boundaries, the start offset must be a modulus of 512 and the end offset must be a modulus of 512 - 1. Examples of valid byte ranges are 0-511, 512-1023, etc.

Header	Variable Name	Type	Operations	Description
CamelAzureStorageBlobCommitBlobBlockListLater	BlobConstants.COMMIT_BLOCK_LIST_LATER	boolean	stageBlockBlobList	When is set to true , the staged blocks will not be committed directly.
CamelAzureStorageBlobCreateAppendBlob	BlobConstants.CREATE_APPEND_BLOB	boolean	commitAppendBlob	When is set to true , the append blocks will be created when committing append blocks.
CamelAzureStorageBlobCreatePageBlob	BlobConstants.CREATE_PAGE_BLOB	boolean	uploadPageBlob	When is set to true , the page blob will be created when uploading page blob.
CamelAzureStorageBlobBlockListType	BlobConstants.BLOCK_LIST_TYPE	BlockListType	getBlobBlockList	Specifies which type of blocks to return.
CamelAzureStorageBlobPageBlobSize	BlobConstants.PAGE_BLOB_SIZE	Long	createPageBlob , resizePageBlob	Specifies the maximum size for the page blob, up to 8 TB. The page blob size must be aligned to a 512-byte boundary.
CamelAzureStorageBlobSequenceNumber	BlobConstants.BLOB_SEQUENCE_NUMBER	Long	createPageBlob	A user-controlled value that you can use to track requests. The value of the sequence number must be between 0 and $2^{63} - 1$. The default value is 0.

Header	Variable Name	Type	Operations	Description
CamelAzureStorageBlobDeleteSnapshotsOptionType	BlobConstants.DELETE_SNAPSHOT_OPTION_TYPE	DeleteSnapshotOptionType	deleteBlob	Specifies the behavior for deleting the snapshots on this blob. <code>\{Include}</code> will delete the base blob and all snapshots. <code>\{Only}</code> will delete only the snapshots. If a snapshot is being deleted, you must pass null.
CamelAzureStorageBlobListBlobContainersOptions	BlobConstants.LIST_BLOB_CONTAINERS_OPTIONS	ListBlobContainersOptions	listBlobContainers	A <code>\{@link ListBlobContainersOptions}</code> which specifies what data should be returned by the service.
CamelAzureStorageBlobParallelTransferOptions	BlobConstants.PARALLEL_TRANSFER_OPTIONS	ParallelTransferOptions	downloadBlobToFile	<code>\{@link ParallelTransferOptions}</code> to use to download to file. Number of parallel transfers parameter is ignored.
CamelAzureStorageBlobFileDir	BlobConstants.FILE_DIR	String	downloadBlobToFile	The file directory where the downloaded blobs will be saved to.
CamelAzureStorageBlobDownloadLinkExpiration	BlobConstants.DOWNLOAD_LINK_EXPIRATION	Long	downloadLink	Override the default expiration (millis) of URL download link.
CamelAzureStorageBlobBlobName	BlobConstants.BLOB_NAME	String	Operations related to blob	Override/set the blob name on the exchange headers.
CamelAzureStorageBlobContainerName	BlobConstants.BLOB_CONTAINER_NAME	String	Operations related to container and blob	Override/set the container name on the exchange headers.

Header	Variable Name	Type	Operations	Description
CamelAzureStorageBlobOperation	BlobConstants.BLOB_OPERATION	BlobOperations Definition	All	Specify the producer operation to execute, please see the doc on this page related to producer operation.
CamelAzureStorageBlobRegex	BlobConstants.REGEX	String	listBlobs, getBlob	Filters the results to return only blobs whose names match the specified regular expression. May be null to return all. If both prefix and regex are set, regex takes the priority and prefix is ignored.
CamelAzureStorageBlobChangeFeedStartTime	BlobConstants.CHANGE_FEED_START_TIME	OffsetDateTime	getChangeFeed	It filters the results to return events approximately after the start time. Note: A few events belonging to the previous hour can also be returned. A few events belonging to this hour can be missing; to ensure all events from the hour are returned, round the start time down by an hour.

Header	Variable Name	Type	Operations	Description
CamelAzureStorageBlobChangeFeedEndTime	BlobConstants.CHANGE_FEED_END_TIME	OffsetDateTime	getChangeFeed	It filters the results to return events approximately before the end time. Note: A few events belonging to the next hour can also be returned. A few events belonging to this hour can be missing; to ensure all events from the hour are returned, round the end time up by an hour.
CamelAzureStorageBlobChangeFeedContext	BlobConstants.CHANGE_FEED_CONTEXT	Context	getChangeFeed	This gives additional context that is passed through the Http pipeline during the service call.
CamelAzureStorageBlobSourceBlobAccountName	BlobConstants.SOURCE_BLOB_ACCOUNT_NAME	String	copyBlob	The source blob account name to be used as source account name in a copy blob operation
CamelAzureStorageBlobSourceBlobContainerName	BlobConstants.SOURCE_BLOB_CONTAINER_NAME	String	copyBlob	The source blob container name to be used as source container name in a copy blob operation

15.6.2. Message headers set by either component producer or consumer

Header	Variable Name	Type	Description
CamelAzureStorageBlobAccessTier	BlobConstants.ACCESS_TIER	AccessTier	Access tier of the blob.

Header	Variable Name	Type	Description
CamelAzureStorageBlobAccessTierChangeTime	BlobConstants.ACCESS_TIER_CHANGE_TIME	OffsetDateTime	Datetime when the access tier of the blob last changed.
CamelAzureStorageBlobArchiveStatus	BlobConstants.ARCHIVE_STATUS	ArchiveStatus	Archive status of the blob.
CamelAzureStorageBlobCreationTime	BlobConstants.CREATION_TIME	OffsetDateTime	Creation time of the blob.
CamelAzureStorageBlobSequenceNumber	BlobConstants.BLOB_SEQUENCE_NUMBER	Long	The current sequence number for a page blob.
CamelAzureStorageBlobBlobSize	BlobConstants.BLOB_SIZE	long	The size of the blob.
CamelAzureStorageBlobBlobType	BlobConstants.BLOB_TYPE	BlobType	The type of the blob.
CamelAzureStorageBlobCacheControl	BlobConstants.CACHE_CONTROL	String	Cache control specified for the blob.
CamelAzureStorageBlobCommittedBlockCount	BlobConstants.COMMITTED_BLOCK_COUNT	Integer	Number of blocks committed to an append blob
CamelAzureStorageBlobContentDisposition	BlobConstants.CONTENT_DISPOSITION	String	Content disposition specified for the blob.
CamelAzureStorageBlobContentEncoding	BlobConstants.CONTENT_ENCODING	String	Content encoding specified for the blob.
CamelAzureStorageBlobContentLanguage	BlobConstants.CONTENT_LANGUAGE	String	Content language specified for the blob.

Header	Variable Name	Type	Description
CamelAzureStorageBlobContentMd5	BlobConstants.CONTENT_MD5	byte[]	Content MD5 specified for the blob.
CamelAzureStorageBlobContentType	BlobConstants.CONTENT_TYPE	String	Content type specified for the blob.
CamelAzureStorageBlobCopyCompletionTime	BlobConstants.COPY_COMPILATION_TIME	OffsetDateTime	Datetime when the last copy operation on the blob completed.
CamelAzureStorageBlobCopyDestinationSnapshot	BlobConstants.COPY_DESTINATION_SNAPSHOT	String	Snapshot identifier of the last incremental copy snapshot for the blob.
CamelAzureStorageBlobCopyId	BlobConstants.COPY_ID	String	Identifier of the last copy operation performed on the blob.
CamelAzureStorageBlobCopyProgress	BlobConstants.COPY_PROGRESS	String	Progress of the last copy operation performed on the blob.
CamelAzureStorageBlobCopySource	BlobConstants.COPY_SOURCE	String	Source of the last copy operation performed on the blob.
CamelAzureStorageBlobCopyStatus	BlobConstants.COPY_STATUS	CopyStatusType	Status of the last copy operation performed on the blob.
CamelAzureStorageBlobCopyStatusDescription	BlobConstants.COPY_STATUS_DESCRIPTION	String	Description of the last copy operation on the blob.
CamelAzureStorageBlobETag	BlobConstants.E_TAG	String	The E Tag of the blob
CamelAzureStorageBlobsAccessTierInferred	BlobConstants.IS_ACCESS_TIER_INFERRED	boolean	Flag indicating if the access tier of the blob was inferred from properties of the blob.
CamelAzureStorageBlobsIncrementalCopy	BlobConstants.IS_INCREMENTAL_COPY	boolean	Flag indicating if the blob was incrementally copied.

Header	Variable Name	Type	Description
CamelAzureStorageBlobsServerEncrypted	BlobConstants.IS_SERVER_ENCRYPTED	boolean	Flag indicating if the blob's content is encrypted on the server.
CamelAzureStorageBlobLastModified	BlobConstants.LAST_MODIFIED	OffsetDateTime	Datetime when the blob was last modified.
CamelAzureStorageBlobLeaseDuration	BlobConstants.LEASE_DURATION	LeaseDurationType	Type of lease on the blob.
CamelAzureStorageBlobLeaseState	BlobConstants.LEASE_STATE	LeaseStateType	State of the lease on the blob.
CamelAzureStorageBlobLeaseStatus	BlobConstants.LEASE_STATUS	LeaseStatusType	Status of the lease on the blob.
CamelAzureStorageBlobMetadata	BlobConstants.METADATA	Map<String, String>	Additional metadata associated with the blob.
CamelAzureStorageBlobAppendOffset	BlobConstants.APPEND_OFFSET	String	The offset at which the block was committed to the block blob.
CamelAzureStorageBlobFileName	BlobConstants.FILE_NAME	String	The downloaded filename from the operation downloadBlobToFile .
CamelAzureStorageBlobDownloadLink	BlobConstants.DOWNLOAD_LINK	String	The download link generated by downloadLink operation.
CamelAzureStorageBlobRawHttpHeaders	BlobConstants.RAW_HTTP_HEADERS	HttpHeaders	Returns non-parsed httpHeaders that can be used by the user.

15.6.3. Advanced Azure Storage Blob configuration

If your Camel Application is running behind a firewall or if you need to have more control over the **BlobServiceClient** instance configuration, you can create your own instance:

```
StorageSharedKeyCredential credential = new StorageSharedKeyCredential("yourAccountName",
```

```

"yourAccessKey");
String uri = String.format("https://%s.blob.core.windows.net", "yourAccountName");

BlobServiceClient client = new BlobServiceClientBuilder()
    .endpoint(uri)
    .credential(credential)
    .buildClient();
// This is camel context
context.getRegistry().bind("client", client);

```

Then refer to this instance in your Camel **azure-storage-blob** component configuration:

```

from("azure-storage-blob://cameldev/container1?blobName=myblob&serviceClient=#client")
.to("mock:result");

```

15.6.4. Automatic detection of BlobServiceClient client in registry

The component is capable of detecting the presence of an BlobServiceClient bean into the registry. If it's the only instance of that type it will be used as client and you won't have to define it as uri parameter, like the example above. This may be really useful for smarter configuration of the endpoint.

15.6.5. Azure Storage Blob Producer operations

Camel Azure Storage Blob component provides wide range of operations on the producer side:

Operations on the service level

For these operations, **accountName** is **required**.

Operation	Description
listBlobContainers	Get the content of the blob. You can restrict the output of this operation to a blob range.
getChangeFeed	Returns transaction logs of all the changes that occur to the blobs and the blob metadata in your storage account. The change feed provides ordered, guaranteed, durable, immutable, read-only log of these changes.

Operations on the container level

For these operations, **accountName** and **containerName** are **required**.

Operation	Description
createBlobContainer	Creates a new container within a storage account. If a container with the same name already exists, the producer will ignore it.
deleteBlobContainer	Deletes the specified container in the storage account. If the container doesn't exist the operation fails.
listBlobs	Returns a list of blobs in this container, with folder structures flattened.

Operations on the blob level

For these operations, **accountName**, **containerName** and **blobName** are required.

Operation	Blob Type	Description
getBlob	Common	Get the content of the blob. You can restrict the output of this operation to a blob range.
deleteBlob	Common	Delete a blob.
downloadBlobToFile	Common	Downloads the entire blob into a file specified by the path. The file will be created and must not exist, if the file already exists a <code>{@link FileAlreadyExistsException}</code> will be thrown.
downloadLink	Common	Generates the download link for the specified blob using shared access signatures (SAS). This by default only limit to 1hour of allowed access. However, you can override the default expiration duration through the headers.
uploadBlockBlob	BlockBlob	Creates a new block blob, or updates the content of an existing block blob. Updating an existing block blob overwrites any existing metadata on the blob. Partial updates are not supported with <code>PutBlob</code> ; the content of the existing blob is overwritten with the new content.
stageBlockBlobList	BlockBlob	Uploads the specified block to the block blob's "staging area" to be later committed by a call to <code>commitBlobBlockList</code> . However in case header <code>CamelAzureStorageBlobCommitBlobBlockListLater</code> or config <code>commitBlockListLater</code> is set to false, this will commit the blocks immediately after staging the blocks.
commitBlobBlockList	BlockBlob	Writes a blob by specifying the list of block IDs that are to make up the blob. In order to be written as part of a blob, a block must have been successfully written to the server in a prior <code>stageBlockBlobList</code> operation. You can call <code>commitBlobBlockList</code> to update a blob by uploading only those blocks that have changed, then committing the new and existing blocks together. Any blocks not specified in the block list and permanently deleted.
getBlobBlockList	BlockBlob	Returns the list of blocks that have been uploaded as part of a block blob using the specified block list filter.

Operation	Blob Type	Description
createAppendBlob	AppendBlob	Creates a 0-length append blob. Call <code>commitAppendBlob</code> operation to append data to an append blob.
commitAppendBlob	AppendBlob	Commits a new block of data to the end of the existing append blob. In case of header CamelAzureStorageBlobCreateAppendBlob or config createAppendBlob is set to true, it will attempt to create the appendBlob through internal call to createAppendBlob operation first before committing.
createPageBlob	PageBlob	Creates a page blob of the specified length. Call uploadPageBlob operation to upload data data to a page blob.
uploadPageBlob	PageBlob	Writes one or more pages to the page blob. The write size must be a multiple of 512. In case of header CamelAzureStorageBlobCreatePageBlob or config createPageBlob is set to true, it will attempt to create the appendBlob through internal call to createPageBlob operation first before uploading.
resizePageBlob	PageBlob	Resizes the page blob to the specified size (which must be a multiple of 512).
clearPageBlob	PageBlob	Frees the specified pages from the page blob. The size of the range must be a multiple of 512.
getPageBlobRanges	PageBlob	Returns the list of valid page ranges for a page blob or snapshot of a page blob.
copyBlob	Common	Copy a blob from one container to another one, even from different accounts.

Refer to the example section in this page to learn how to use these operations into your camel application.

15.6.6. Consumer Examples

To consume a blob into a file using file component, this can be done like this:

```
from("azure-storage-blob://camelazure/container1?
blobName=hello.txt&accountName=yourAccountName&accessKey=yourAccessKey")
to("file://blobdirectory");
```

However, you can also write to file directly without using the file component, you will need to specify **fileDir** folder path in order to save your blob in your machine.

```
from("azure-storage-blob://camelazure/container1?
blobName=hello.txt&accountName=yourAccountName&accessKey=yourAccessKey&fileDir=/var/to/awesome/dir").
to("mock:results");
```

Also, the component supports batch consumer, hence you can consume multiple blobs with only specifying the container name, the consumer will return multiple exchanges depending on the number of the blobs in the container.

Example

```
from("azure-storage-blob://camelazure/container1?
accountName=yourAccountName&accessKey=yourAccessKey&fileDir=/var/to/awesome/dir").
to("mock:results");
```

15.6.7. Producer Operations Examples

- **listBlobContainers**

```
from("direct:start")
.process(exchange -> {
    // set the header you want the producer to evaluate, refer to the previous
    // section to learn about the headers that can be set
    // e.g:
    exchange.getIn().setHeader(BlobConstants.LIST_BLOB_CONTAINERS_OPTIONS, new
ListBlobContainersOptions().setMaxResultsPerPage(10));
})
.to("azure-storage-blob://camelazure?operation=listBlobContainers&client&serviceClient=#client")
.to("mock:result");
```

- **createBlobContainer**

```
from("direct:start")
.process(exchange -> {
    // set the header you want the producer to evaluate, refer to the previous
    // section to learn about the headers that can be set
    // e.g:
    exchange.getIn().setHeader(BlobConstants.BLOB_CONTAINER_NAME, "newContainerName");
})
.to("azure-storage-blob://camelazure/container1?
operation=createBlobContainer&serviceClient=#client")
.to("mock:result");
```

- **deleteBlobContainer:**

```
from("direct:start")
.process(exchange -> {
    // set the header you want the producer to evaluate, refer to the previous
    // section to learn about the headers that can be set
    // e.g:
    exchange.getIn().setHeader(BlobConstants.BLOB_CONTAINER_NAME, "overridenName");
```

```

    })
    .to("azure-storage-blob://camelazure/container1?
operation=deleteBlobContainer&serviceClient=#client")
    .to("mock:result");

```

- **listBlobs:**

```

from("direct:start")
    .process(exchange -> {
        // set the header you want the producer to evaluate, refer to the previous
        // section to learn about the headers that can be set
        // e.g:
        exchange.getIn().setHeader(BlobConstants.BLOB_CONTAINER_NAME, "overridenName");
    })
    .to("azure-storage-blob://camelazure/container1?operation=listBlobs&serviceClient=#client")
    .to("mock:result");

```

- **getBlob:**

We can either set an **outputStream** in the exchange body and write the data to it. E.g:

```

from("direct:start")
    .process(exchange -> {
        // set the header you want the producer to evaluate, refer to the previous
        // section to learn about the headers that can be set
        // e.g:
        exchange.getIn().setHeader(BlobConstants.BLOB_CONTAINER_NAME, "overridenName");

        // set our body
        exchange.getIn().setBody(outputStream);
    })
    .to("azure-storage-blob://camelazure/container1?
blobName=blob&operation=getBlob&serviceClient=#client")
    .to("mock:result");

```

If we don't set a body, then this operation will give us an **InputStream** instance which can proceed further downstream:

```

from("direct:start")
    .to("azure-storage-blob://camelazure/container1?
blobName=blob&operation=getBlob&serviceClient=#client")
    .process(exchange -> {
        InputStream inputStream = exchange.getMessage().getBody(InputStream.class);
        // We use Apache common IO for simplicity, but you are free to do whatever dealing
        // with inputStream
        System.out.println(IUtils.toString(inputStream, StandardCharsets.UTF_8.name()));
    })
    .to("mock:result");

```

- **deleteBlob:**

```

from("direct:start")
    .process(exchange -> {
        // set the header you want the producer to evaluate, refer to the previous

```

```
// section to learn about the headers that can be set
// e.g:
exchange.getIn().setHeader(BlobConstants.BLOB_NAME, "overridenName");
})
.to("azure-storage-blob://camelazure/container1?
blobName=blob&operation=deleteBlob&serviceClient=#client")
.to("mock:result");
```

- **downloadBlobToFile:**

```
from("direct:start")
.process(exchange -> {
    // set the header you want the producer to evaluate, refer to the previous
    // section to learn about the headers that can be set
    // e.g:
    exchange.getIn().setHeader(BlobConstants.BLOB_NAME, "overridenName");
})
.to("azure-storage-blob://camelazure/container1?
blobName=blob&operation=downloadBlobToFile&fileDir=/var/mydir&serviceClient=#client")
.to("mock:result");
```

- **downloadLink**

```
from("direct:start")
.to("azure-storage-blob://camelazure/container1?
blobName=blob&operation=downloadLink&serviceClient=#client")
.process(exchange -> {
    String link = exchange.getMessage().getHeader(BlobConstants.DOWNLOAD_LINK,
String.class);
    System.out.println("My link " + link);
})
.to("mock:result");
```

- **uploadBlockBlob**

```
from("direct:start")
.process(exchange -> {
    // set the header you want the producer to evaluate, refer to the previous
    // section to learn about the headers that can be set
    // e.g:
    exchange.getIn().setHeader(BlobConstants.BLOB_NAME, "overridenName");
    exchange.getIn().setBody("Block Blob");
})
.to("azure-storage-blob://camelazure/container1?
blobName=blob&operation=uploadBlockBlob&serviceClient=#client")
.to("mock:result");
```

- **stageBlockBlobList**

```
from("direct:start")
.process(exchange -> {
    final List<BlobBlock> blocks = new LinkedList<>();
    blocks.add(BlobBlock.createBlobBlock(new ByteArrayInputStream("Hello".getBytes())));
    blocks.add(BlobBlock.createBlobBlock(new ByteArrayInputStream("From".getBytes())));
```

```

        blocks.add(BlobBlock.createBlobBlock(new ByteArrayInputStream("Camel".getBytes())));

        exchange.getIn().setBody(blocks);
    })
    .to("azure-storage-blob://camelazure/container1?
blobName=blob&operation=stageBlockBlobList&serviceClient=#client")
    .to("mock:result");

```

- **commitBlockBlobList**

```

from("direct:start")
    .process(exchange -> {
        // We assume here you have the knowledge of these blocks you want to commit
        final List<Block> blocksIds = new LinkedList<>();
        blocksIds.add(new Block().setName("id-1"));
        blocksIds.add(new Block().setName("id-2"));
        blocksIds.add(new Block().setName("id-3"));

        exchange.getIn().setBody(blocksIds);
    })
    .to("azure-storage-blob://camelazure/container1?
blobName=blob&operation=commitBlockBlobList&serviceClient=#client")
    .to("mock:result");

```

- **getBlobBlockList**

```

from("direct:start")
    .to("azure-storage-blob://camelazure/container1?
blobName=blob&operation=getBlobBlockList&serviceClient=#client")
    .log("${body}")
    .to("mock:result");

```

- **createAppendBlob**

```

from("direct:start")
    .to("azure-storage-blob://camelazure/container1?
blobName=blob&operation=createAppendBlob&serviceClient=#client")
    .to("mock:result");

```

- **commitAppendBlob**

```

from("direct:start")
    .process(exchange -> {
        final String data = "Hello world from my awesome tests!";
        final InputStream dataStream = new
ByteArrayInputStream(data.getBytes(StandardCharsets.UTF_8));

        exchange.getIn().setBody(dataStream);

        // of course you can set whatever headers you like, refer to the headers section to learn more
    })
    .to("azure-storage-blob://camelazure/container1?
blobName=blob&operation=commitAppendBlob&serviceClient=#client")
    .to("mock:result");

```

- **createPageBlob**

```
from("direct:start")
.to("azure-storage-blob://camelazure/container1?
blobName=blob&operation=createPageBlob&serviceClient=#client")
.to("mock:result");
```

- **uploadPageBlob**

```
from("direct:start")
.process(exchange -> {
    byte[] dataBytes = new byte[512]; // we set range for the page from 0-511
    new Random().nextBytes(dataBytes);
    final InputStream dataStream = new ByteArrayInputStream(dataBytes);
    final PageRange pageRange = new PageRange().setStart(0).setEnd(511);

    exchange.getIn().setHeader(BlobConstants.PAGE_BLOB_RANGE, pageRange);
    exchange.getIn().setBody(dataStream);
})
.to("azure-storage-blob://camelazure/container1?
blobName=blob&operation=uploadPageBlob&serviceClient=#client")
.to("mock:result");
```

- **resizePageBlob**

```
from("direct:start")
.process(exchange -> {
    final PageRange pageRange = new PageRange().setStart(0).setEnd(511);

    exchange.getIn().setHeader(BlobConstants.PAGE_BLOB_RANGE, pageRange);
})
.to("azure-storage-blob://camelazure/container1?
blobName=blob&operation=resizePageBlob&serviceClient=#client")
.to("mock:result");
```

- **clearPageBlob**

```
from("direct:start")
.process(exchange -> {
    final PageRange pageRange = new PageRange().setStart(0).setEnd(511);

    exchange.getIn().setHeader(BlobConstants.PAGE_BLOB_RANGE, pageRange);
})
.to("azure-storage-blob://camelazure/container1?
blobName=blob&operation=clearPageBlob&serviceClient=#client")
.to("mock:result");
```

- **getPageBlobRanges**

```
from("direct:start")
.process(exchange -> {
    final PageRange pageRange = new PageRange().setStart(0).setEnd(511);

    exchange.getIn().setHeader(BlobConstants.PAGE_BLOB_RANGE, pageRange);
```

```

    })
    .to("azure-storage-blob://camelazure/container1?
blobName=blob&operation=getPageBlobRanges&serviceClient=#client")
    .log("${body}")
    .to("mock:result");

```

- **copyBlob**

```

from("direct:copyBlob")
    .process(exchange -> {
        exchange.getIn().setHeader(BlobConstants.BLOB_NAME, "file.txt");
        exchange.getMessage().setHeader(BlobConstants.SOURCE_BLOB_CONTAINER_NAME,
"containerblob1");
        exchange.getMessage().setHeader(BlobConstants.SOURCE_BLOB_ACCOUNT_NAME,
"account");
    })
    .to("azure-storage-blob://account/containerblob2?
operation=copyBlob&sourceBlobAccessKey=RAW(accessKey)")
    .to("mock:result");

```

In this way the file.txt in the container containerblob1 of the account 'account', will be copied to the container containerblob2 of the same account.

15.6.8. SAS Token generation example

SAS Blob Container tokens can be generated programmatically or via Azure UI. To generate the token with java code, the following can be done:

```

BlobContainerClient blobClient = new BlobContainerClientBuilder()
    .endpoint(String.format("https://%s.blob.core.windows.net/%s", accountName, accessKey))
    .containerName(containerName)
    .credential(new StorageSharedKeyCredential(accountName, accessKey))
    .buildClient();

// Create a SAS token that's valid for 1 day, as an example
OffsetDateTime expiryTime = OffsetDateTime.now().plusDays(1);

// Assign permissions to the SAS token
BlobContainerSasPermission blobContainerSasPermission = new
BlobContainerSasPermission()
    .setWritePermission(true)
    .setListPermission(true)
    .setCreatePermission(true)
    .setDeletePermission(true)
    .setAddPermission(true)
    .setReadPermission(true);

BlobServiceSasSignatureValues sasSignatureValues = new
BlobServiceSasSignatureValues(expiryTime, blobContainerSasPermission);

return blobClient.generateSas(sasSignatureValues);

```

The generated SAS token can be then stored to an **application.properties** file so that it can be loaded by the camel route, for example:

```
camel.component.azure-storage-blob.sas-token=MY_TOKEN_HERE

from("direct:copyBlob")
.to("azure-storage-blob://account/containerblob2?
operation=uploadBlockBlob&credentialType=AZURE_SAS")
```

15.7. SPRING BOOT AUTO-CONFIGURATION

The component supports 36 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.azure-storage-blob.access-key</code>	Access key for the associated azure account name to be used for authentication with azure blob services.		String
<code>camel.component.azure-storage-blob.autowired-enabled</code>	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
<code>camel.component.azure-storage-blob.blob-name</code>	The blob name, to consume specific blob from a container. However on producer, is only required for the operations on the blob level.		String
<code>camel.component.azure-storage-blob.blob-offset</code>	Set the blob offset for the upload or download operations, default is 0.	0	Long
<code>camel.component.azure-storage-blob.blob-sequence-number</code>	A user-controlled value that you can use to track requests. The value of the sequence number must be between 0 and 263 - 1. The default value is 0.	0	Long
<code>camel.component.azure-storage-blob.blob-type</code>	The blob type in order to initiate the appropriate settings for each blob type.		BlobType
<code>camel.component.azure-storage-blob.block-list-type</code>	Specifies which type of blocks to return.		BlockListType

Name	Description	Default	Type
camel.component.azure-storage-blob.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.azure-storage-blob.change-feed-context	When using <code>getChangeFeed</code> producer operation, this gives additional context that is passed through the Http pipeline during the service call. The option is a <code>com.azure.core.util.Context</code> type.		Context
camel.component.azure-storage-blob.change-feed-end-time	When using <code>getChangeFeed</code> producer operation, this filters the results to return events approximately before the end time. Note: A few events belonging to the next hour can also be returned. A few events belonging to this hour can be missing; to ensure all events from the hour are returned, round the end time up by an hour. The option is a <code>java.time.OffsetDateTime</code> type.		OffsetDateTime
camel.component.azure-storage-blob.change-feed-start-time	When using <code>getChangeFeed</code> producer operation, this filters the results to return events approximately after the start time. Note: A few events belonging to the previous hour can also be returned. A few events belonging to this hour can be missing; to ensure all events from the hour are returned, round the start time down by an hour. The option is a <code>java.time.OffsetDateTime</code> type.		OffsetDateTime
camel.component.azure-storage-blob.close-stream-after-read	Close the stream after read or keep it open, default is true.	true	Boolean
camel.component.azure-storage-blob.close-stream-after-write	Close the stream after write or keep it open, default is true.	true	Boolean

Name	Description	Default	Type
<code>camel.component.azure-storage-blob.commit-block-list-later</code>	When is set to true, the staged blocks will not be committed directly.	true	Boolean
<code>camel.component.azure-storage-blob.configuration</code>	The component configurations. The option is a <code>org.apache.camel.component.azure.storage.blob.BlobConfiguration</code> type.		BlobConfiguration
<code>camel.component.azure-storage-blob.create-append-blob</code>	When is set to true, the append blocks will be created when committing append blocks.	true	Boolean
<code>camel.component.azure-storage-blob.create-page-blob</code>	When is set to true, the page blob will be created when uploading page blob.	true	Boolean
<code>camel.component.azure-storage-blob.credential-type</code>	Determines the credential strategy to adopt.		CredentialType
<code>camel.component.azure-storage-blob.credentials</code>	<code>StorageSharedKeyCredential</code> can be injected to create the azure client, this holds the important authentication information. The option is a <code>com.azure.storage.common.StorageSharedKeyCredential</code> type.		StorageSharedKeyCredential
<code>camel.component.azure-storage-blob.data-count</code>	How many bytes to include in the range. Must be greater than or equal to 0 if specified.		Long
<code>camel.component.azure-storage-blob.download-link-expiration</code>	Override the default expiration (millis) of URL download link.		Long
<code>camel.component.azure-storage-blob.enabled</code>	Whether to enable auto configuration of the <code>azure-storage-blob</code> component. This is enabled by default.		Boolean
<code>camel.component.azure-storage-blob.file-dir</code>	The file directory where the downloaded blobs will be saved to, this can be used in both, producer and consumer.		String

Name	Description	Default	Type
<code>camel.component.azure-storage-blob.health-check-consumer-enabled</code>	Used for enabling or disabling all consumer based health checks from this component.	true	Boolean
<code>camel.component.azure-storage-blob.health-check-producer-enabled</code>	Used for enabling or disabling all producer based health checks from this component. Notice: Camel has by default disabled all producer based health-checks. You can turn on producer checks globally by setting <code>camel.health.producersEnabled=true</code> .	true	Boolean
<code>camel.component.azure-storage-blob.lazy-start-producer</code>	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
<code>camel.component.azure-storage-blob.max-results-per-page</code>	Specifies the maximum number of blobs to return, including all BlobPrefix elements. If the request does not specify <code>maxResultsPerPage</code> or specifies a value greater than 5,000, the server will return up to 5,000 items.		Integer
<code>camel.component.azure-storage-blob.max-retry-requests</code>	Specifies the maximum number of additional HTTP Get requests that will be made while reading the data from a response body.	0	Integer
<code>camel.component.azure-storage-blob.operation</code>	The blob operation that can be used with this component on the producer.		BlobOperationsDefinition
<code>camel.component.azure-storage-blob.page-blob-size</code>	Specifies the maximum size for the page blob, up to 8 TB. The page blob size must be aligned to a 512-byte boundary.	512	Long
<code>camel.component.azure-storage-blob.prefix</code>	Filters the results to return only blobs whose names begin with the specified prefix. May be null to return all blobs.		String

Name	Description	Default	Type
camel.component.azure-storage-blob.regex	Filters the results to return only blobs whose names match the specified regular expression. May be null to return all if both prefix and regex are set, regex takes the priority and prefix is ignored.		String
camel.component.azure-storage-blob.sas-token	Set a SAS Token in case of usage of Shared Access Signature		String
camel.component.azure-storage-blob.service-client	Client to a storage account. This client does not hold any state about a particular storage account but is instead a convenient way of sending off appropriate requests to the resource on the service. It may also be used to construct URLs to blobs and containers. This client contains operations on a service account. Operations on a container are available on BlobContainerClient through BlobServiceClient#getBlobContainerClient(String), and operations on a blob are available on BlobClient through BlobContainerClient#getBlobClient(String). The option is a com.azure.storage.blob.BlobServiceClient type.		BlobServiceClient
camel.component.azure-storage-blob.source-blob-access-key	Source Blob Access Key: for copyblob operation, sadly, we need to have an accessKey for the source blob we want to copy Passing an accessKey as header, it's unsafe so we could set as key.		String
camel.component.azure-storage-blob.timeout	An optional timeout value beyond which a RuntimeException will be raised. The option is a java.time.Duration type.		Duration

CHAPTER 16. AZURE STORAGE QUEUE SERVICE

Both producer and consumer are supported

The Azure Storage Queue component supports storing and retrieving the messages to/from [Azure Storage Queue](#) service using **Azure APIs v12**. However in case of versions above v12, we will see if this component can adopt these changes depending on how much breaking changes can result.

Prerequisites

You must have a valid Windows Azure Storage account. More information is available at [Azure Documentation Portal](#).

16.1. DEPENDENCIES

When using **azure-storage-queue** with Red Hat build of Camel Spring Boot, add the following Maven dependency to your **pom.xml** to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-azure-storage-queue-starter</artifactId>
</dependency>
```

16.2. URI FORMAT

```
azure-storage-queue://accountName[/queueName][?options]
```

In case of consumer, `accountName` and `queueName` are required. In case of producer, it depends on the operation that being requested, for example if operation is on a service level, e.b: `listQueues`, only `accountName` is required, but in case of operation being requested on the queue level, for example, `createQueue`, `sendMessage`.. etc, both `accountName` and `queueName` are required.

The queue will be created if it does not already exist. You can append query options to the URI in the following format,

?options=value&option2=value&...

16.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

16.3.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).
- directly in the Java code.

16.3.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

16.4. COMPONENT OPTIONS

The Azure Storage Queue Service component supports 15 options, which are listed below.

Name	Description	Default	Type
configuration (common)	The component configurations.		QueueConfigurati on
serviceClient (common)	Autowired Service client to a storage account to interact with the queue service. This client does not hold any state about a particular storage account but is instead a convenient way of sending off appropriate requests to the resource on the service. This client contains all the operations for interacting with a queue account in Azure Storage. Operations allowed by the client are creating, listing, and deleting queues, retrieving and updating properties of the account, and retrieving statistics of the account.		QueueServiceClie nt

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
createQueue (producer)	When is set to true, the queue will be automatically created when sending messages to the queue.	false	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
operation (producer)	Queue service operation hint to the producer. Enum values: • <code>listQueues</code> • <code>createQueue</code> • <code>deleteQueue</code> • <code>clearQueue</code> • <code>sendMessage</code> • <code>deleteMessage</code> • <code>receiveMessages</code> • <code>peekMessages</code> • <code>updateMessage</code>		QueueOperationDefinition

Name	Description	Default	Type
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
maxMessages (queue)	Maximum number of messages to get, if there are less messages exist in the queue than requested all the messages will be returned. If left empty only 1 message will be retrieved, the allowed range is 1 to 32 messages.	1	Integer
messageId (queue)	The ID of the message to be deleted or updated.		String
popReceipt (queue)	Unique identifier that must match for the message to be deleted or updated.		String
timeout (queue)	An optional timeout applied to the operation. If a response is not returned before the timeout concludes a RuntimeException will be thrown.		Duration
timeToLive (queue)	How long the message will stay alive in the queue. If unset the value will default to 7 days, if -1 is passed the message will not expire. The time to live must be -1 or any positive number. The format should be in this form: PnDTnHnMn.nS., e.g: PT20.345S – parses as 20.345 seconds, P2D – parses as 2 days However, in case you are using EndpointDsl/ComponentDsl, you can do something like Duration.ofSeconds() since these Java APIs are typesafe.		Duration
visibilityTimeout (queue)	The timeout period for how long the message is invisible in the queue. The timeout must be between 1 seconds and 7 days. The format should be in this form: PnDTnHnMn.nS., e.g: PT20.345S – parses as 20.345 seconds, P2D – parses as 2 days However, in case you are using EndpointDsl/ComponentDsl, you can do something like Duration.ofSeconds() since these Java APIs are typesafe.		Duration
accessKey (security)	Access key for the associated azure account name to be used for authentication with azure queue services.		String
credentials (security)	StorageSharedKeyCredential can be injected to create the azure client, this holds the important authentication information.		StorageSharedKey Credential

16.5. ENDPOINT OPTIONS

The Azure Storage Queue Service endpoint is configured using URI syntax:

```
azure-storage-queue:accountName/queueName
```

with the following path and query parameters:

16.5.1. Path Parameters (2 parameters)

Name	Description	Default	Type
accountName (common)	Azure account name to be used for authentication with azure queue services.		String
queueName (common)	The queue resource name.		String

16.5.2. Query Parameters (31 parameters)

Name	Description	Default	Type
serviceClient (common)	Autowired Service client to a storage account to interact with the queue service. This client does not hold any state about a particular storage account but is instead a convenient way of sending off appropriate requests to the resource on the service. This client contains all the operations for interacting with a queue account in Azure Storage. Operations allowed by the client are creating, listing, and deleting queues, retrieving and updating properties of the account, and retrieving statistics of the account.		QueueServiceClient
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean

Name	Description	Default	Type
exceptionHandler (consumer (advanced))	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at <code>WARN</code> or <code>ERROR</code> level and ignored.		<code>ExceptionHandler</code>
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • <code>InOnly</code> • <code>InOut</code> • <code>InOptionalOut</code>		<code>ExchangePattern</code>
pollStrategy (consumer (advanced))	A pluggable <code>org.apache.camel.PollingConsumerPollingStrategy</code> allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an <code>Exchange</code> have been created and being routed in Camel.		<code>PollingConsumerPollStrategy</code>
createQueue (producer)	When is set to true, the queue will be automatically created when sending messages to the queue.	false	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow <code>CamelContext</code> and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

Name	Description	Default	Type
operation (producer)	Queue service operation hint to the producer. Enum values: • listQueues • createQueue • deleteQueue • clearQueue • sendMessage • deleteMessage • receiveMessages • peekMessages • updateMessage		QueueOperationDefinition
maxMessages (queue)	Maximum number of messages to get, if there are less messages exist in the queue than requested all the messages will be returned. If left empty only 1 message will be retrieved, the allowed range is 1 to 32 messages.	1	Integer
messageId (queue)	The ID of the message to be deleted or updated.		String
popReceipt (queue)	Unique identifier that must match for the message to be deleted or updated.		String
timeout (queue)	An optional timeout applied to the operation. If a response is not returned before the timeout concludes a RuntimeException will be thrown.		Duration
timeToLive (queue)	How long the message will stay alive in the queue. If unset the value will default to 7 days, if -1 is passed the message will not expire. The time to live must be -1 or any positive number. The format should be in this form: PnDTnHnMn.nS., e.g: PT20.345S – parses as 20.345 seconds, P2D – parses as 2 days However, in case you are using EndpointDsl/ComponentDsl, you can do something like Duration.ofSeconds() since these Java APIs are typesafe.		Duration

Name	Description	Default	Type
visibilityTimeout (queue)	The timeout period for how long the message is invisible in the queue. The timeout must be between 1 seconds and 7 days. The format should be in this form: PnDTnHnMn.nS, e.g: PT20.345S – parses as 20.345 seconds, P2D – parses as 2 days However, in case you are using EndpointDsl/ComponentDsl, you can do something like Duration.ofSeconds() since these Java APIs are typesafe.		Duration
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.		int
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.		int
delay (scheduler)	Milliseconds before the next poll.	500	long
greedy (scheduler)	If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts.	1000	long
repeatCount (scheduler)	Specifies a maximum limit of number of fires. So if you set it to 1, the scheduler will only fire once. If you set it to 5, it will only fire five times. A value of zero or negative means fire forever.	0	long

Name	Description	Default	Type
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that. Enum values: • TRACE • DEBUG • INFO • WARN • ERROR • OFF	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz component. Use value spring or quartz for built in scheduler.	none	Object
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for initialDelay and delay options. Enum values: • NANOSECONDS • MICROSECONDS • MILLISECONDS • SECONDS • MINUTES • HOURS • DAYS	MILLIS ECON DS	TimeUnit

Name	Description	Default	Type
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See <code>ScheduledExecutorService</code> in JDK for details.	true	boolean
accessKey (security)	Access key for the associated azure account name to be used for authentication with azure queue services.		String
credentials (security)	<code>StorageSharedKeyCredential</code> can be injected to create the azure client, this holds the important authentication information.		<code>StorageSharedKeyCredential</code>

Required information options

To use this component, you have 3 options in order to provide the required Azure authentication information:

- Provide **accountName** and **accessKey** for your Azure account, this is the simplest way to get started. The accessKey can be generated through your Azure portal.
- Provide a [StorageSharedKeyCredential](#) instance which can be provided into **credentials** option.
- Provide a [QueueServiceClient](#) instance which can be provided into **serviceClient**. Note: You don't need to create a specific client, e.g: `QueueClient`, the `QueueServiceClient` represents the upper level which can be used to retrieve lower level clients.

16.6. USAGE

For example in order to get a message content from the queue **messageQueue** in the **storageAccount** storage account and, use the following snippet:

```
from("azure-storage-queue://storageAccount/messageQueue?accessKey=yourAccessKey").
to("file://queuedirectory");
```

16.6.1. Message headers evaluated by the component producer

Header	Variable Name	Type	Operations	Description
CamelAzureStorageQueueSegmentOptions	QueueConstants.QUEUES_SEGMENT_OPTIONS	QueuesSegmentOptions	listQueues	Options for listing queues
CamelAzureStorageQueueTimeout	QueueConstants.TIMEOUT	Duration	All	An optional timeout value beyond which a <code>\{@link RuntimeException}</code> will be raised.

Header	Variable Name	Type	Operations	Description
CamelAzureStorageQueueMetadata	QueueConstants.METADATA	Map<String,String>	createQueue	Metadata to associate with the queue
CamelAzureStorageQueueTimeToLive	QueueConstants.TIME_TO_LIVE	Duration	sendMessage	How long the message will stay alive in the queue. If unset the value will default to 7 days, if -1 is passed the message will not expire. The time to live must be -1 or any positive number.
CamelAzureStorageQueueVisibilityTimeout	QueueConstants.VISIBILITY_TIMEOUT	Duration	sendMessage, receiveMessages, updateMessage	The timeout period for how long the message is invisible in the queue. If unset the value will default to 0 and the message will be instantly visible. The timeout must be between 0 seconds and 7 days.
CamelAzureStorageQueueCreateQueue	QueueConstants.CREATE_QUEUE	boolean	sendMessage	When is set to true , the queue will be automatically created when sending messages to the queue.
CamelAzureStorageQueuePopReceipt	QueueConstants.POP_RECEIPT	String	deleteMessage, updateMessage	Unique identifier that must match for the message to be deleted or updated.
CamelAzureStorageQueueMessageId	QueueConstants.MESSAGE_ID	String	deleteMessage, updateMessage	The ID of the message to be deleted or updated.

Header	Variable Name	Type	Operations	Description
CamelAzureStorageQueueMaxMessages	QueueConstants.MAX_MESSAGES	Integer	receiveMessages, peekMessages	Maximum number of messages to get, if there are less messages exist in the queue than requested all the messages will be returned. If left empty only 1 message will be retrieved, the allowed range is 1 to 32 messages.
CamelAzureStorageQueueOperation	QueueConstants.QUEUE_OPERATION	QueueOperationDefinition	All	Specify the producer operation to execute, please see the doc on this page related to producer operation.
CamelAzureStorageQueueName	QueueConstants.QUEUE_NAME	String	All	Override the queue name.

16.6.2. Message headers set by either component producer or consumer

Header	Variable Name	Type	Description
CamelAzureStorageQueueMessageId	QueueConstants.MESSAGE_ID	String	The ID of message that being sent to the queue.
CamelAzureStorageQueueInsertionTime	QueueConstants.INSERTION_TIME	OffsetDateTime	The time the Message was inserted into the Queue.
CamelAzureStorageQueueExpirationTime	QueueConstants.EXPIRATION_TIME	OffsetDateTime	The time that the Message will expire and be automatically deleted.
CamelAzureStorageQueuePopReceipt	QueueConstants.POP_RECEIPT	String	This value is required to delete/update the Message. If deletion fails using this popreceipt then the message has been dequeued by another client.

Header	Variable Name	Type	Description
CamelAzureStorageQueueTimeNextVisible	QueueConstants.TIME_NEXT_VISIBLE	OffsetDateTime	The time that the message will again become visible in the Queue.
CamelAzureStorageQueueDequeueCount	QueueConstants.DEQUEUE_COUNT	long	The number of times the message has been dequeued.
CamelAzureStorageQueueRawHttpHeaders	QueueConstants.RAW_HTTP_HEADERS	HttpHeaders	Returns non-parsed httpHeaders that can be used by the user.

16.6.3. Advanced Azure Storage Queue configuration

If your Camel Application is running behind a firewall or if you need to have more control over the **QueueServiceClient** instance configuration, you can create your own instance:

```
StorageSharedKeyCredential credential = new StorageSharedKeyCredential("yourAccountName",
"yourAccessKey");
String uri = String.format("https://%s.queue.core.windows.net", "yourAccountName");

QueueServiceClient client = new QueueServiceClientBuilder()
    .endpoint(uri)
    .credential(credential)
    .buildClient();
// This is camel context
context.getRegistry().bind("client", client);
```

Then refer to this instance in your Camel **azure-storage-queue** component configuration:

```
from("azure-storage-queue://cameldev/queue1?serviceClient=#client")
.to("file://outputFolder?fileName=output.txt&fileExist=Append");
```

16.6.4. Automatic detection of QueueServiceClient client in registry

The component is capable of detecting the presence of an QueueServiceClient bean into the registry. If it's the only instance of that type it will be used as client and you won't have to define it as uri parameter, like the example above. This may be really useful for smarter configuration of the endpoint.

16.6.5. Azure Storage Queue Producer operations

Camel Azure Storage Queue component provides wide range of operations on the producer side:

Operations on the service level

For these operations, **accountName** is required.

Operation	Description
listQueues	Lists the queues in the storage account that pass the filter starting at the specified marker.

Operations on the queue level

For these operations, **accountName** and **queueName** are required.

Operation	Description
createQueue	Creates a new queue.
deleteQueue	Permanently deletes the queue.
clearQueue	Deletes all messages in the queue..
sendMessage	Default Producer Operation Sends a message with a given time-to-live and a timeout period where the message is invisible in the queue. The message text is evaluated from the exchange message body. By default, if the queue doesn't exist, it will create an empty queue first. If you want to disable this, set the config createQueue or header CamelAzureStorageQueueCreateQueue to false .
deleteMessage	Deletes the specified message in the queue.
receiveMessages	Retrieves up to the maximum number of messages from the queue and hides them from other operations for the timeout period. However it will not dequeue the message from the queue due to reliability reasons.
peekMessages	Peek messages from the front of the queue up to the maximum number of messages.
updateMessage	Updates the specific message in the queue with a new message and resets the visibility timeout. The message text is evaluated from the exchange message body.

Refer to the example section in this page to learn how to use these operations into your camel application.

16.6.6. Consumer Examples

To consume a queue into a file component with maximum 5 messages in one batch, this can be done like this:

```
from("azure-storage-queue://cameldev/queue1?serviceClient=#client&maxMessages=5")
.to("file://outputFolder?fileName=output.txt&fileExist=Append");
```

16.6.7. Producer Operations Examples

- **listQueues:**

```
from("direct:start")
  .process(exchange -> {
    // set the header you want the producer to evaluate, refer to the previous
    // section to learn about the headers that can be set
    // e.g, to only returns list of queues with 'awesome' prefix:
    exchange.getIn().setHeader(QueueConstants.QUEUES_SEGMENT_OPTIONS, new
QueuesSegmentOptions().setPrefix("awesome"));
  })
  .to("azure-storage-queue://cameldev?serviceClient=#client&operation=listQueues")
  .log("${body}")
  .to("mock:result");
```

- **createQueue:**

```
from("direct:start")
  .process(exchange -> {
    // set the header you want the producer to evaluate, refer to the previous
    // section to learn about the headers that can be set
    // e.g:
    exchange.getIn().setHeader(QueueConstants.QUEUE_NAME, "overrideName");
  })
  .to("azure-storage-queue://cameldev/test?serviceClient=#client&operation=createQueue");
```

- **deleteQueue:**

```
from("direct:start")
  .process(exchange -> {
    // set the header you want the producer to evaluate, refer to the previous
    // section to learn about the headers that can be set
    // e.g:
    exchange.getIn().setHeader(QueueConstants.QUEUE_NAME, "overrideName");
  })
  .to("azure-storage-queue://cameldev/test?serviceClient=#client&operation=deleteQueue");
```

- **clearQueue:**

```
from("direct:start")
  .process(exchange -> {
    // set the header you want the producer to evaluate, refer to the previous
    // section to learn about the headers that can be set
    // e.g:
    exchange.getIn().setHeader(QueueConstants.QUEUE_NAME, "overrideName");
  })
  .to("azure-storage-queue://cameldev/test?serviceClient=#client&operation=clearQueue");
```

- **sendMessage:**

```
from("direct:start")
  .process(exchange -> {
    // set the header you want the producer to evaluate, refer to the previous
```

```

// section to learn about the headers that can be set
// e.g:
exchange.getIn().setBody("message to send");
// we set a visibility of 1 min
exchange.getIn().setHeader(QueueConstants.VISIBILITY_TIMEOUT, Duration.ofMinutes(1));
})
.to("azure-storage-queue://cameldev/test?serviceClient=#client");

```

- **deleteMessage:**

```

from("direct:start")
.process(exchange -> {
    // set the header you want the producer to evaluate, refer to the previous
    // section to learn about the headers that can be set
    // e.g:
    // Mandatory header:
    exchange.getIn().setHeader(QueueConstants.MESSAGE_ID, "1");
    // Mandatory header:
    exchange.getIn().setHeader(QueueConstants.POP_RECEIPT, "PAAAAHEEERXXX-1");
})
.to("azure-storage-queue://cameldev/test?serviceClient=#client&operation=deleteMessage");

```

- **receiveMessages:**

```

from("direct:start")
.to("azure-storage-queue://cameldev/test?serviceClient=#client&operation=receiveMessages")
.process(exchange -> {
    final List<QueueMessageItem> messageItems = exchange.getMessage().getBody(List.class);
    messageItems.forEach(messageItem -> System.out.println(messageItem.getMessageText()));
})
.to("mock:result");

```

- **peekMessages:**

```

from("direct:start")
.to("azure-storage-queue://cameldev/test?serviceClient=#client&operation=peekMessages")
.process(exchange -> {
    final List<PeekedMessageItem> messageItems = exchange.getMessage().getBody(List.class);
    messageItems.forEach(messageItem -> System.out.println(messageItem.getMessageText()));
})
.to("mock:result");

```

- **updateMessage:**

```

from("direct:start")
.process(exchange -> {
    // set the header you want the producer to evaluate, refer to the previous
    // section to learn about the headers that can be set
    // e.g:
    exchange.getIn().setBody("new message text");
    // Mandatory header:
    exchange.getIn().setHeader(QueueConstants.MESSAGE_ID, "1");
    // Mandatory header:
    exchange.getIn().setHeader(QueueConstants.POP_RECEIPT, "PAAAAHEEERXXX-1");
})

```

```
// Mandatory header:
exchange.getIn().setHeader(QueueConstants.VISIBILITY_TIMEOUT, Duration.ofMinutes(1));
})
.to("azure-storage-queue://cameldev/test?serviceClient=#client&operation=updateMessage");
```

16.6.8. Development Notes (Important)

When developing on this component, you will need to obtain your Azure accessKey in order to run the integration tests. In addition to the mocked unit tests you **will need to run the integration tests with every change you make or even client upgrade as the Azure client can break things even on minor versions upgrade**. To run the integration tests, on this component directory, run the following maven command:

```
mvn verify -PfullTests -DaccountName=myacc -DaccessKey=mykey
```

Whereby **accountName** is your Azure account name and **accessKey** is the access key being generated from Azure portal.

16.7. SPRING BOOT AUTO-CONFIGURATION

The component supports 16 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.azure-storage-queue.access-key</code>	Access key for the associated azure account name to be used for authentication with azure queue services.		String
<code>camel.component.azure-storage-queue.autowired-enabled</code>	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
<code>camel.component.azure-storage-queue.bridge-error-handler</code>	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
<code>camel.component.azure-storage-queue.configuration</code>	The component configurations. The option is a <code>org.apache.camel.component.azure.storage.queue.QueueConfiguration</code> type.		QueueConfiguration

Name	Description	Default	Type
<code>camel.component.azure-storage-queue.create-queue</code>	When is set to true, the queue will be automatically created when sending messages to the queue.	false	Boolean
<code>camel.component.azure-storage-queue.credentials</code>	StorageSharedKeyCredential can be injected to create the azure client, this holds the important authentication information. The option is a <code>com.azure.storage.common.StorageSharedKeyCredential</code> type.		StorageSharedKeyCredential
<code>camel.component.azure-storage-queue.enabled</code>	Whether to enable auto configuration of the azure-storage-queue component. This is enabled by default.		Boolean
<code>camel.component.azure-storage-queue.lazy-start-producer</code>	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
<code>camel.component.azure-storage-queue.max-messages</code>	Maximum number of messages to get, if there are less messages exist in the queue than requested all the messages will be returned. If left empty only 1 message will be retrieved, the allowed range is 1 to 32 messages.	1	Integer
<code>camel.component.azure-storage-queue.message-id</code>	The ID of the message to be deleted or updated.		String
<code>camel.component.azure-storage-queue.operation</code>	Queue service operation hint to the producer.		QueueOperationDefinition
<code>camel.component.azure-storage-queue.pop-receipt</code>	Unique identifier that must match for the message to be deleted or updated.		String

Name	Description	Default	Type
camel.component.azure-storage-queue.service-client	Service client to a storage account to interact with the queue service. This client does not hold any state about a particular storage account but is instead a convenient way of sending off appropriate requests to the resource on the service. This client contains all the operations for interacting with a queue account in Azure Storage. Operations allowed by the client are creating, listing, and deleting queues, retrieving and updating properties of the account, and retrieving statistics of the account. The option is a <code>com.azure.storage.queue.QueueServiceClient</code> type.		QueueServiceClient
camel.component.azure-storage-queue.time-to-live	How long the message will stay alive in the queue. If unset the value will default to 7 days, if -1 is passed the message will not expire. The time to live must be -1 or any positive number. The format should be in this form: <code>PnDTnHnMn.nS</code> , e.g: <code>PT20.345S</code> – parses as 20.345 seconds, <code>P2D</code> – parses as 2 days However, in case you are using <code>EndpointDsl/ComponentDsl</code> , you can do something like <code>Duration.ofSeconds()</code> since these Java APIs are typesafe. The option is a <code>java.time.Duration</code> type.		Duration
camel.component.azure-storage-queue.timeout	An optional timeout applied to the operation. If a response is not returned before the timeout concludes a <code>RuntimeException</code> will be thrown. The option is a <code>java.time.Duration</code> type.		Duration
camel.component.azure-storage-queue.visibility-timeout	The timeout period for how long the message is invisible in the queue. The timeout must be between 1 seconds and 7 days. The format should be in this form: <code>PnDTnHnMn.nS</code> , e.g: <code>PT20.345S</code> – parses as 20.345 seconds, <code>P2D</code> – parses as 2 days However, in case you are using <code>EndpointDsl/ComponentDsl</code> , you can do something like <code>Duration.ofSeconds()</code> since these Java APIs are typesafe. The option is a <code>java.time.Duration</code> type.		Duration

CHAPTER 17. BEAN

Only producer is supported

The Bean component binds beans to Camel message exchanges.

17.1. DEPENDENCIES

When using **bean** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-bean-starter</artifactId>
</dependency>
```

17.2. URI FORMAT

```
bean:beanName[?options]
```

Where **beanID** can be any string which is used to look up the bean in the Registry

17.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

17.3.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).
- directly in the Java code.

17.3.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

17.4. COMPONENT OPTIONS

The Bean component supports 4 options, which are listed below.

Name	Description	Default	Type
cache (producer)	Deprecated Use singleton option instead.	true	Boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

Name	Description	Default	Type
scope (producer)	Scope of bean. When using singleton scope (default) the bean is created or looked up only once and reused for the lifetime of the endpoint. The bean should be thread-safe in case concurrent threads is calling the bean at the same time. When using request scope the bean is created or looked up once per request (exchange). This can be used if you want to store state on a bean while processing a request and you want to call the same bean instance multiple times while processing the request. The bean does not have to be thread-safe as the instance is only called from the same request. When using delegate scope, then the bean will be looked up or created per call. However in case of lookup then this is delegated to the bean registry such as Spring or CDI (if in use), which depends on their configuration can act as either singleton or prototype scope. so when using prototype then this depends on the delegated registry. Enum values: • Singleton • Request • Prototype	Singleton	BeanScope
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

17.5. ENDPOINT OPTIONS

The Bean endpoint is configured using URI syntax:

```
bean:beanName
```

with the following path and query parameters:

17.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
beanName (common)	Required Sets the name of the bean to invoke.		String

17.5.2. Query Parameters (5 parameters)

Name	Description	Default	Type
cache (common)	Deprecated Use scope option instead.		Boolean
method (common)	Sets the name of the method to invoke on the bean.		String
scope (common)	Scope of bean. When using singleton scope (default) the bean is created or looked up only once and reused for the lifetime of the endpoint. The bean should be thread-safe in case concurrent threads is calling the bean at the same time. When using request scope the bean is created or looked up once per request (exchange). This can be used if you want to store state on a bean while processing a request and you want to call the same bean instance multiple times while processing the request. The bean does not have to be thread-safe as the instance is only called from the same request. When using prototype scope, then the bean will be looked up or created per call. However in case of lookup then this is delegated to the bean registry such as Spring or CDI (if in use), which depends on their configuration can act as either singleton or prototype scope. so when using prototype then this depends on the delegated registry. Enum values: • Singleton • Request • Prototype	Singleton	BeanScope

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
parameters (advanced)	Used for configuring additional properties on the bean.		Map

17.6. EXAMPLES

The object instance that is used to consume messages must be explicitly registered with the Registry. For example, if you are using Spring you must define the bean in the Spring configuration XML file.

You can also register beans manually via Camel's **Registry** with the **bind** method.

Once an endpoint has been registered, you can build Camel routes that use it to process exchanges.

A **bean:** endpoint cannot be defined as the input to the route; i.e. you cannot consume from it, you can only route from some inbound message Endpoint to the bean endpoint as output. So consider using a **direct:** or **queue:** endpoint as the input.

You can use the **createProxy()** methods on [ProxyHelper](#) to create a proxy that will generate exchanges and send them to any endpoint:

And the same route using XML DSL:

```
<route>
  <from uri="direct:hello"/>
  <to uri="bean:bye"/>
</route>
```

17.7. BEAN AS ENDPOINT

Camel also supports invoking [Bean](#) as an Endpoint. What happens is that when the exchange is routed to the **myBean** Camel will use the Bean Binding to invoke the bean. The source for the bean is just a plain POJO.

Camel will use Bean Binding to invoke the **sayHello** method, by converting the Exchange's In body to the **String** type and storing the output of the method on the Exchange Out body.

17.8. JAVA DSL BEAN SYNTAX

Java DSL comes with syntactic sugar for the component. Instead of specifying the bean explicitly as the endpoint (i.e. `to("bean:beanName")`) you can use the following syntax:

```
// Send message to the bean endpoint
// and invoke method resolved using Bean Binding.
from("direct:start").bean("beanName");

// Send message to the bean endpoint
// and invoke given method.
from("direct:start").bean("beanName", "methodName");
```

Instead of passing name of the reference to the bean (so that Camel will lookup for it in the registry), you can specify the bean itself:

```
// Send message to the given bean instance.
from("direct:start").bean(new ExampleBean());

// Explicit selection of bean method to be invoked.
from("direct:start").bean(new ExampleBean(), "methodName");

// Camel will create the instance of bean and cache it for you.
from("direct:start").bean(ExampleBean.class);
```

17.9. BEAN BINDING

How bean methods to be invoked are chosen (if they are not specified explicitly through the **method** parameter) and how parameter values are constructed from the Message are all defined by the Bean Binding mechanism which is used throughout all of the various Bean Integration mechanisms in Camel.

17.10. SPRING BOOT AUTO-CONFIGURATION

The component supports 13 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.bean.autowired-enabled</code>	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
<code>camel.component.bean.enabled</code>	Whether to enable auto configuration of the bean component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component. .bean.lazy-start- producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component. .bean.scope	Scope of bean. When using singleton scope (default) the bean is created or looked up only once and reused for the lifetime of the endpoint. The bean should be thread-safe in case concurrent threads is calling the bean at the same time. When using request scope the bean is created or looked up once per request (exchange). This can be used if you want to store state on a bean while processing a request and you want to call the same bean instance multiple times while processing the request. The bean does not have to be thread-safe as the instance is only called from the same request. When using delegate scope, then the bean will be looked up or created per call. However in case of lookup then this is delegated to the bean registry such as Spring or CDI (if in use), which depends on their configuration can act as either singleton or prototype scope. so when using prototype then this depends on the delegated registry.		BeanScope
camel.component. .class.autowired- enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component. .class.enabled	Whether to enable auto configuration of the class component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.scope	Scope of bean. When using singleton scope (default) the bean is created or looked up only once and reused for the lifetime of the endpoint. The bean should be thread-safe in case concurrent threads is calling the bean at the same time. When using request scope the bean is created or looked up once per request (exchange). This can be used if you want to store state on a bean while processing a request and you want to call the same bean instance multiple times while processing the request. The bean does not have to be thread-safe as the instance is only called from the same request. When using delegate scope, then the bean will be looked up or created per call. However in case of lookup then this is delegated to the bean registry such as Spring or CDI (if in use), which depends on their configuration can act as either singleton or prototype scope. so when using prototype then this depends on the delegated registry.		BeanScope
camel.language.bean.enabled	Whether to enable auto configuration of the bean language. This is enabled by default.		Boolean

Name	Description	Default	Type
<code>camel.language.bean.scope</code>	Scope of bean. When using singleton scope (default) the bean is created or looked up only once and reused for the lifetime of the endpoint. The bean should be thread-safe in case concurrent threads is calling the bean at the same time. When using request scope the bean is created or looked up once per request (exchange). This can be used if you want to store state on a bean while processing a request and you want to call the same bean instance multiple times while processing the request. The bean does not have to be thread-safe as the instance is only called from the same request. When using prototype scope, then the bean will be looked up or created per call. However in case of lookup then this is delegated to the bean registry such as Spring or CDI (if in use), which depends on their configuration can act as either singleton or prototype scope. So when using prototype scope then this depends on the bean registry implementation.	Singleton	String
<code>camel.language.bean.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
<code>camel.component.bean.cache</code>	Deprecated Use singleton option instead.	true	Boolean
<code>camel.component.class.cache</code>	Deprecated Use singleton option instead.	true	Boolean

CHAPTER 18. BEANIO

Since Camel 2.10

The BeanIO Data Format uses [BeanIO](#) to handle flat payloads (such as XML, CSV, delimited, or fixed length formats).

BeanIO is configured using a mapping XML file where you define the mapping from the flat format to Objects (POJOs). This mapping file is mandatory to use.

18.1. DEPENDENCIES

When using beanio with Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-beanio-starter</artifactId>
</dependency>
```

18.2. OPTIONS

The BeanIO dataformat supports 8 options, which are listed below.

Name	Default	Java Type	Description
mapping (common)		String	Required The BeanIO mapping file. Is by default loaded from

Name	Default	Java Type	Description
			path. You can prefix with file; http; or class path: to denote from where to load the mapping file.

Name	Default	Java Type	Description
streamName (common)		String	Required The name of the stream to use.
ignoreUnidentifiedRecords (common)	false	Boolean	Whether to ignore unidentified records.

Name	Default	Java Type	Description
<code>ignoreUnexpectedRecords</code> (common)	false	Boolean	Whether to ignore unexpected records.
<code>ignoreInvalidRecords</code> (common)	false	Boolean	Whether to ignore invalid records.

Name	Default	Java Type	Description
encoding (advanced)		String	The charset to use. Is by default the JVM platform default charset.
beanReaderErrorHandlerType (advanced)		String	To use a custom or g.a.p.a.ch.e.c.a.m.e.l.d.a.t.a.f.o.r.m.a.t.b.e.a.n.i.o.

Name	Default	Java Type	BeanIO Description
			Handler as error handler while parsing. Configure the fully qualified class name of the error handler. Notice the options ignore

Name	Default	Java Type	Description
			Records, ignore Unexpected Records, and ignore invalid Records may not be in use when you use a custom error handler.

Name marshalSingleObject (advanced)	Default	Java Type	Description
			ns co ntr ols wh et he r to un ma rs hal as a list of ob jec ts or as a sin gl e ob jec t on ly. Th e for m er is th e de fa ult m od e, an d th e lat ter is

Name	Default	Java Type	Description
			defined in special use-cases wherever be an omaps the Camel messages to a single POJO bean.

18.3. USAGE

An example of a [mapping file is here](#).

To use the **BeanIODataFormat** you need to configure the data format with the mapping file, as well the name of the stream.

This can be done as shown below. The streamName is **employeeFile**.

- Java
- XML

```
DataFormat format = new BeanIODataFormat(
    "org/apache/camel/dataformat/beanio/mappings.xml",
    "employeeFile");

// a route which uses the bean io data format to format the CSV data
// to java objects
from("direct:unmarshal")
    .unmarshal(format)
    // and then split the message body, so we get a message for each row
    .split(body())
    .to("mock:beanio-unmarshal");

// convert a list of java objects back to flat format
from("direct:marshal")
    .marshal(format)
    .to("mock:beanio-marshal");
```

```
<route>
  <from uri="direct:unmarshal"/>
  <unmarshal>
    <beanio mapping="org/apache/camel/dataformat/beanio/mappings.xml"
streamName="employeeFile"/>
  </unmarshal>
  <split>
    <simple>${body}</simple>
    <to uri="mock:beanio-unmarshal"/>
  </split>
</route>

<route>
  <from uri="direct:marshal"/>
  <marshal>
    <beanio mapping="org/apache/camel/dataformat/beanio/mappings.xml"
streamName="employeeFile"/>
  </marshal>
  <to uri="mock:beanio-marshal"/>
</route>
```

To use the BeanIO data format in XML, you need to configure it using the **<beanio>** XML tag as shown below. The routes are similar to the example above.

The first route is for transforming CSV data into a **List<Employee>** Java objects. Which we then split, so the mock endpoint receives a message for each row.

The second route is for the reverse operation, to transform a **List<Employee>** into a stream of CSV data.

The CSV data could, for example, be as below:

Joe,Smith,Developer,75000,10012009
 Jane,Doe,Architect,80000,01152008
 Jon,Anderson,Manager,85000,03182007

18.4. SPRING BOOT AUTO-CONFIGURATION

The component supports 9 options, which are listed below.

Name	Description	Default	Type
camel.dataformat.beanio.bean-reader-error-handler-type	To use a custom <code>org.apache.camel.dataformat.beanio.BeanIOErrorHandler</code> as error handler while parsing. Configure the fully qualified class name of the error handler. Notice the options <code>ignoreUnidentifiedRecords</code> , <code>ignoreUnexpectedRecords</code> , and <code>ignoreInvalidRecords</code> may not be in use when you use a custom error handler.		String
camel.dataformat.beanio.enabled	Whether to enable auto configuration of the beanio data format. This is enabled by default.		Boolean
camel.dataformat.beanio.encoding	The charset to use. Is by default the JVM platform default charset.		String
camel.dataformat.beanio.ignore-invalid-records	Whether to ignore invalid records.	false	Boolean
camel.dataformat.beanio.ignore-unexpected-records	Whether to ignore unexpected records.	false	Boolean
camel.dataformat.beanio.ignore-unidentified-records	Whether to ignore unidentified records.	false	Boolean
camel.dataformat.beanio.mapping	The BeanIO mapping file. Is by default loaded from the classpath. You can prefix with <code>file:</code> , <code>http:</code> , or <code>classpath:</code> to denote from where to load the mapping file.		String
camel.dataformat.beanio.stream-name	The name of the stream to use.		String

Name	Description	Default	Type
camel.dataformat.beanio.unmarshal-single-object	This option controls whether to unmarshal as a list of objects or as a single object only. The former is the default mode, and the latter is only intended in special use-cases where beanio maps the Camel message to a single POJO bean.	false	Boolean

CHAPTER 19. BEAN VALIDATOR

Only producer is supported

The Validator component performs bean validation of the message body using the Java Bean Validation API (). Camel uses the reference implementation, which is [Hibernate Validator](#).

19.1. DEPENDENCIES

When using **bean-validator** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-bean-validator-starter</artifactId>
</dependency>
```

19.2. URI FORMAT

```
bean-validator:label[?options]
```

Where **label** is an arbitrary text value describing the endpoint. You can append query options to the URI in the following format,

?option=value&option=value&...

19.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

19.3.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).
- directly in the Java code.

19.3.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

19.4. COMPONENT OPTIONS

The Bean Validator component supports 8 options, which are listed below.

Name	Description	Default	Type
ignoreXmlConfiguration (producer)	Whether to ignore data from the META-INF/validation.xml file.	false	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
constraintValidatorFactory (advanced)	To use a custom ConstraintValidatorFactory.		ConstraintValidatorFactory

Name	Description	Default	Type
messageInterpolator (advanced)	To use a custom MessageInterpolator.		MessageInterpolator
traversableResolver (advanced)	To use a custom TraversableResolver.		TraversableResolver
validationProviderResolver (advanced)	To use a a custom ValidationProviderResolver.		ValidationProviderResolver
validatorFactory (advanced)	Autowired To use a custom ValidatorFactory.		ValidatorFactory

19.5. ENDPOINT OPTIONS

The Bean Validator endpoint is configured using URI syntax:

```
bean-validator:label
```

with the following path and query parameters:

19.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
label (producer)	Required Where label is an arbitrary text value describing the endpoint.		String

19.5.2. Query Parameters (8 parameters)

Name	Description	Default	Type
group (producer)	To use a custom validation group.	javax.validation.groups.Default	String
ignoreXmlConfiguration (producer)	Whether to ignore data from the META-INF/validation.xml file.	false	boolean

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
constraintValidatorFactory (advanced)	To use a custom ConstraintValidatorFactory.		ConstraintValidatorFactory
messageInterpolator (advanced)	To use a custom MessageInterpolator.		MessageInterpolator
traversableResolver (advanced)	To use a custom TraversableResolver.		TraversableResolver
validationProviderResolver (advanced)	To use a a custom ValidationProviderResolver.		ValidationProviderResolver
validatorFactory (advanced)	To use a custom ValidatorFactory.		ValidatorFactory

19.6. EXAMPLE

Assumed we have a java bean with the following annotations

Car.java

```
public class Car {

    @NotNull
    private String manufacturer;

    @NotNull
    @Size(min = 5, max = 14, groups = OptionalChecks.class)
    private String licensePlate;

    // getter and setter
}
```

and an interface definition for our custom validation group

OptionalChecks.java

```
public interface OptionalChecks {  
}
```

with the following Camel route, only the **@NotNull** constraints on the attributes `manufacturer` and `licensePlate` will be validated (Camel uses the default group **javax.validation.groups.Default**).

```
from("direct:start")  
  .to("bean-validator://x")  
  .to("mock:end")
```

If you want to check the constraints from the group **OptionalChecks**, you have to define the route like this

```
from("direct:start")  
  .to("bean-validator://x?group=OptionalChecks")  
  .to("mock:end")
```

If you want to check the constraints from both groups, you have to define a new interface first

AllChecks.java

```
@GroupSequence({Default.class, OptionalChecks.class})  
public interface AllChecks {  
}
```

and then your route definition should look like this

```
from("direct:start")  
  .to("bean-validator://x?group=AllChecks")  
  .to("mock:end")
```

And if you have to provide your own message interpolator, traversable resolver and constraint validator factory, you have to write a route like this

```
<bean id="myMessageInterpolator" class="my.ConstraintValidatorFactory" />  
<bean id="myTraversableResolver" class="my.TraversableResolver" />  
<bean id="myConstraintValidatorFactory" class="my.ConstraintValidatorFactory" />
```

```
from("direct:start")  
  .to("bean-validator://x?group=AllChecks&messageInterpolator=#myMessageInterpolator  
&traversableResolver=#myTraversableResolver&constraintValidatorFactory=#myConstraintValidatorFactory")  
  .to("mock:end")
```

It's also possible to describe your constraints as XML and not as Java annotations. In this case, you have to provide the file **META-INF/validation.xml** which could look like this

validation.xml

-

```

<validation-config
  xmlns="http://jboss.org/xml/ns/javax/validation/configuration"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://jboss.org/xml/ns/javax/validation/configuration">

  <default-provider>org.hibernate.validator.HibernateValidator</default-provider>
  <message-
interpolator>org.hibernate.validator.engine.ResourceBundleMessageInterpolator</message-
interpolator>
  <traversable-
resolver>org.hibernate.validator.engine.resolver.DefaultTraversableResolver</traversable-resolver>
  <constraint-validator-
factory>org.hibernate.validator.engine.ConstraintValidatorFactoryImpl</constraint-validator-factory>
  <constraint-mapping>/constraints-car.xml</constraint-mapping>

</validation-config>

```

and the **constraints-car.xml** file

constraints-car.xml

```

<constraint-mappings xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://jboss.org/xml/ns/javax/validation/mapping validation-mapping-1.0.xsd"
  xmlns="http://jboss.org/xml/ns/javax/validation/mapping">

  <default-package>org.apache.camel.component.bean.validator</default-package>

  <bean class="CarWithoutAnnotations" ignore-annotations="true">
    <field name="manufacturer">
      <constraint annotation="javax.validation.constraints.NotNull" />
    </field>

    <field name="licensePlate">
      <constraint annotation="javax.validation.constraints.NotNull" />

      <constraint annotation="javax.validation.constraints.Size">
        <groups>
          <value>org.apache.camel.component.bean.validator.OptionalChecks</value>
        </groups>
        <element name="min">5</element>
        <element name="max">14</element>
      </constraint>
    </field>
  </bean>
</constraint-mappings>

```

Here is the XML syntax for the example route definition for [OrderedChecks](#).

Note that the body should include an instance of a class to validate.

```

<beans xmlns="http://www.springframework.org/schema/beans"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="
    http://www.springframework.org/schema/beans
    http://www.springframework.org/schema/beans/spring-beans.xsd

```

```

http://camel.apache.org/schema/spring http://camel.apache.org/schema/spring/camel-spring.xsd">

<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="direct:start"/>
    <to uri="bean-validator://x?
group=org.apache.camel.component.bean.validator.OrderedChecks"/>
  </route>
</camelContext>
</beans>

```

19.7. SPRING BOOT AUTO-CONFIGURATION

The component supports 9 options, which are listed below.

Name	Description	Default	Type
camel.component.bean-validator.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.bean-validator.constraint-validator-factory	To use a custom ConstraintValidatorFactory. The option is a <code>javax.validation.ConstraintValidatorFactory</code> type.		ConstraintValidatorFactory
camel.component.bean-validator.enabled	Whether to enable auto configuration of the bean-validator component. This is enabled by default.		Boolean
camel.component.bean-validator.ignore-xml-configuration	Whether to ignore data from the META-INF/validation.xml file.	false	Boolean
camel.component.bean-validator.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component .bean- validator.message- interpolator	To use a custom MessageInterpolator. The option is a javax.validation.MessageInterpolator type.		MessageInterpolator
camel.component .bean- validator.traversa- ble-resolver	To use a custom TraversableResolver. The option is a javax.validation.TraversableResolver type.		TraversableResolv er
camel.component .bean- validator.validatio- n-provider- resolver	To use a a custom ValidationProviderResolver. The option is a javax.validation.ValidationProviderResolver type.		ValidationProvider Resolver
camel.component .bean- validator.validato- r-factory	To use a custom ValidatorFactory. The option is a javax.validation.ValidatorFactory type.		ValidatorFactory

CHAPTER 20. BINDY

The goal of this component is to allow the parsing/binding of non-structured data (or to be more precise non-XML data) to/from Java Beans that have binding mappings defined with annotations. Using Bindy, you can bind data from sources such as :

- CSV records,
- Fixed-length records,
- FIX messages,
- or almost any other non-structured data

to one or many Plain Old Java Object (POJO). Bindy converts the data according to the type of the java property. POJOs can be linked together with one-to-many relationships available in some cases. Moreover, for data type like Date, Double, Float, Integer, Short, Long and BigDecimal, you can provide the pattern to apply during the formatting of the property.

For the BigDecimal numbers, you can also define the precision and the decimal or grouping separators.

Type	Format Type	Pattern example	Link
Date	DateFormat	dd-MM-yyyy	https://docs.oracle.com/en/java/javase/11/docs/api/java.base/java/text/SimpleDateFormat.html
Decimal*	DecimalFormat	##.###.###	https://docs.oracle.com/en/java/javase/11/docs/api/java.base/java/text/DecimalFormat.html

Where Decimal = Double, Integer, Float, Short, Long

Format supported

This first release only support comma separated values fields and key value pair fields (e.g. : FIX messages).

To work with camel-bindy, you must first define your model in a package (e.g. com.acme.model) and for each model class (e.g. Order, Client, Instrument, ...) add the required annotations (described hereafter) to the Class or field.

Multiple models

As you configure bindy using class names instead of package names you can put multiple models in the same package.

20.1. DEPENDENCIES

When using **bindy-csv** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-bindy-starter</artifactId>
</dependency>
```

20.2. OPTIONS

The Bindy dataformat supports 5 options, which are listed below.

Name	Default	Java Type	Description
type		Enum	Required Whether to use Csv, Fixed, or KeyValue. Enum values: • Csv • Fixed • KeyValue
classType		String	Name of model class to use.
locale		String	To configure a default locale to use, such as us for united states. To use the JVM platform default locale then use the name default.
unwrapSingleInstance		Boolean	When unmarshalling should a single instance be unwrapped and returned instead of wrapped in a java.util.List.
allowEmptyStream		Boolean	Whether to allow empty streams in the unmarshal process. If true, no exception will be thrown when a body without records is provided.

20.3. ANNOTATIONS

The annotations created allow to map different concept of your model to the POJO like:

- Type of record (CSV, key value pair (e.g. FIX message), fixed length ...),
- Link (to link object in another object),
- DataField and their properties (int, type, ...),
- KeyValuePairField (for key = value format like we have in FIX financial messages),

- Section (to identify header, body and footer section),
- OneToMany,
- BindyConverter,
- FormatFactories

This section will describe them.

20.3.1.1. CsvRecord

The CsvRecord annotation is used to identified the root class of the model. It represents a record = "a line of a CSV file" and can be linked to several children model classes.

Annotation name	Record type	Level
CsvRecord	CSV	Class

Parameter name	Type	Required	Default value	Info
separator	String	✓		Separator used to split a record in tokens (mandatory) - can be ',' or ';' or 'anything'. The only whitespace character supported is tab (\t). No other whitespace characters (spaces) are not supported. This value is interpreted as a regular expression. If you want to use a sign which has a special meaning in regular expressions, e.g. the ' ' sign, then you have to mask it, like ' '.
allowEmptyStream	boolean		false	The allowEmptyStream parameter will allow to process the unavailable stream for CSV file.
autospanLine	boolean		false	Last record spans rest of line (optional) - if enabled then the last column is auto spanned to end of line, for example if its a comment, etc this allows the line to contain all characters, also the delimiter char.
crLf	String		WINDOWS	Character to be used to add a carriage return after each record (optional) - allow to define the carriage return character to use. If you specify a value other than the three listed before, the value you enter (custom) will be used as the CRLF character(s). Three values can be used : WINDOWS, UNIX, MAC, or custom.
endWithLineBreak	boolean		true	The endWithLineBreak parameter flags if the CSV file should end with a line break or not (optional)

Parameter name	Type	Required	Default value	Info
generateHeaderColumns	boolean		false	The generateHeaderColumns parameter allow to add in the CSV generated the header containing names of the columns
isOrdered	boolean		false	Indicates if the message must be ordered in output
name	String			Name describing the record (optional)
quote	String		"	Whether to marshal columns with the given quote character (optional) – allow to specify a quote character of the fields when CSV is generated. This annotation is associated to the root class of the model and must be declared one time.
quoting	boolean		false	Indicate if the values (and headers) must be quoted when marshaling (optional)
quotingEscaped	boolean		false	Indicate if the values must be escaped when quoting (optional)
removeQuotes	boolean		true	The remove quotes parameter flags if unmarshalling should try to remove quotes for each field
skipField	boolean		false	The skipField parameter will allow to skip fields of a CSV file. If some fields are not necessary, they can be skipped.
skipFirstLine	boolean		false	The skipFirstLine parameter will allow to skip or not the first line of a CSV file. This line often contains columns definition
trimLine	boolean		true	Whether to trim each line (stand and end) before parsing the line into data fields.

case 1: separator = ','

The separator used to segregate the fields in the CSV record is , :

```
10, J, Pauline, M, XD12345678, Fortis Dynamic 15/15, 2500, USD, 08-01-2009
```

```
@CsvRecord( separator = "," )
public Class Order {

}
```

case 2 : separator = ';' ;

Compare to the previous case, the separator here is ; instead of , :

```
10; J; Pauline; M; XD12345678; Fortis Dynamic 15/15; 2500; USD; 08-01-2009
```

```
@CsvRecord( separator = ";" )
public Class Order {

}
```

case 3 : separator = '|' ;

Compare to the previous case, the separator here is | instead of ; :

```
10| J| Pauline| M| XD12345678| Fortis Dynamic 15/15| 2500| USD| 08-01-2009
```

```
@CsvRecord( separator = "|" )
public Class Order {

}
```

case 4 : separator = '\"','\"'**Applies for Camel 2.8.2 or older**

When the field to be parsed of the CSV record contains , or ; which is also used as separator, we should find another strategy to tell camel bindy how to handle this case. To define the field containing the data with a comma, you will use single or double quotes as delimiter (e.g : '10', 'Street 10, NY', 'USA' or "10", "Street 10, NY", "USA").

**NOTE**

In this case, the first and last character of the line which are a single or double quotes will be removed by bindy.

```
"10","J","Pauline"," M","XD12345678","Fortis Dynamic 15,15","2500","USD","08-01-2009"
```

```
@CsvRecord( separator = "\"','\"" )
public Class Order {

}
```

Bindy automatically detects if the record is enclosed with either single or double quotes and automatic remove those quotes when unmarshalling from CSV to Object. Therefore do **not** include the quotes in the separator, but simply do as below:

```
"10","J","Pauline"," M","XD12345678","Fortis Dynamic 15,15","2500","USD","08-01-2009"
```

```
@CsvRecord( separator = "," )
public Class Order {
```

```
}
```

Note that if you want to marshal from Object to CSV and use quotes, then you need to specify which quote character to use, using the **quote** attribute on the **@CsvRecord** as shown below:

```
@CsvRecord( separator = ",", quote = "\"" )
public Class Order {

}
```

case 5 : separator & skipFirstLine

The feature is interesting when the client wants to have in the first line of the file, the name of the data fields :

```
order id, client id, first name, last name, isin code, instrument name, quantity, currency, date
```

To inform bindy that this first line must be skipped during the parsing process, then we use the attribute :

```
@CsvRecord(separator = ",", skipFirstLine = true)
public Class Order {

}
```

case 6 : generateHeaderColumns

To add at the first line of the CSV generated, the attribute generateHeaderColumns must be set to true in the annotation like this :

```
@CsvRecord( generateHeaderColumns = true )
public Class Order {

}
```

As a result, Bindy during the unmarshaling process will generate CSV like this :

```
order id, client id, first name, last name, isin code, instrument name, quantity, currency, date
10, J, Pauline, M, XD12345678, Fortis Dynamic 15/15, 2500, USD, 08-01-2009
```

case 7 : carriage return

If the platform where camel-bindy will run is not Windows but Macintosh or Unix, then you can change the crlf property like this. Three values are available : WINDOWS, UNIX or MAC

```
@CsvRecord(separator = ",", crlf="MAC")
public Class Order {

}
```

Additionally, if for some reason you need to add a different line ending character, you can opt to specify it using the crlf parameter. In the following example, we can end the line with a comma followed by the newline character:

```
■
```

```
@CsvRecord(separator = ",", crlf=",\n")
public Class Order {

}
```

case 8 : isOrdered

Sometimes, the order to follow during the creation of the CSV record from the model is different from the order used during the parsing. Then, in this case, we can use the attribute **isOrdered = true** to indicate this in combination with attribute **position** of the DataField annotation.

```
@CsvRecord(isOrdered = true)
public Class Order {

    @DataField(pos = 1, position = 11)
    private int orderNr;

    @DataField(pos = 2, position = 10)
    private String clientNr;

}
```

NOTE

pos is used to parse the file stream, while **position** is used to generate the CSV.

20.3.2. 2. Link

The link annotation will allow to link objects together.

Annotation name	Record type	Level
Link	all	Class & Property

Parameter name	Type	Required	Default value	Info
linkType	LinkType		OneToOne	Type of link identifying the relation between the classes

Only one-to-one relation is allowed as of the current version.

E.g : If the model class Client is linked to the Order class, then use annotation Link in the Order class like this :

Property Link

```
@CsvRecord(separator = ",")
public class Order {
```

```

@DataField(pos = 1)
private int orderNr;

@Link
private Client client;
}

```

And for the class Client :

Class Link

```

@Link
public class Client {

}

```

20.3.3. 3. DataField

The DataField annotation defines the property of the field. Each datafield is identified by its position in the record, a type (string, int, date, ...) and optionally of a pattern.

Annotation name	Record type	Level
DataField	all	Property

Parameter name	Type	Required	Default value	Info
pos	int	✓		Position of the data in the input record, must start from 1 (mandatory). See the position parameter.
align	String		R	Align the text to the right or left. Use values <code><tt>R</tt></code> or <code><tt>L</tt></code> .
clip	boolean		false	Indicates to clip data in the field if it exceeds the allowed length when using fixed length.
columnName	String			Name of the header column (optional). Uses the name of the property as default. Only applicable when CsvRecord has generateHeaderColumns = true
decimalSeparator	String			Decimal Separator to be used with BigDecimal number
defaultValue	String			Field's default value in case no value is set

Parameter name	Type	Required	Default value	Info
delimiter	String			Optional delimiter to be used if the field has a variable length
groupingSeparator	String			Grouping Separator to be used with BigDecimal number when we would like to format/parse to number with grouping e.g. 123,456.789
impliedDecimalSeparator	boolean		false	Indicates if there is a decimal point implied at a specified location
length	int		0	Length of the data block (number of characters) if the record is set to a fixed length
lengthPos	int		0	Identifies a data field in the record that defines the expected fixed length for this field
method	String			Method name to call to apply such customization on DataField. This must be the method on the datafield itself or you must provide static fully qualified name of the class's method e.g: see unit test <code>org.apache.camel.dataformat.bindy.csv.BindySimpleCsvFunctionWithExternalMethodTest.replaceToBar</code>
name	String			Name of the field (optional)
paddingChar	char			The char to pad with if the record is set to a fixed length
pattern	String			Pattern that the Java formatter (SimpleDateFormat by example) will use to transform the data (optional). If using pattern, then setting locale on bindy data format is recommended. Either set to a known locale such as "us" or use "default" to use platform default locale.
position	int		0	Position of the field in the output message generated (should start from 1). Must be used when the position of the field in the CSV generated (output message) must be different compare to input position (pos). See the pos parameter.
precision	int		0	precision of the <code>{@link java.math.BigDecimal}</code> number to be created

Parameter name	Type	Required	Default value	Info
required	boolean		false	Indicates if the field is mandatory
rounding	String		CEILING	Round mode to be used to round/scale a BigDecimal Values : UP, DOWN, CEILING, FLOOR, HALF_UP, HALF_DOWN, HALF_EVEN, UNNECESSARY e.g : Number = 123456.789, Precision = 2, Rounding = CEILING Result : 123456.79
timezone	String			Timezone to be used.
trim	boolean		false	Indicates if the value should be trimmed

case 1: pos

This parameter/attribute represents the position of the field in the CSV record.

Position

```
@CsvRecord(separator = ";")
public class Order {

    @DataField(pos = 1)
    private int orderNr;

    @DataField(pos = 5)
    private String isinCode;

}
```

As you can see in this example the position starts at **1** but continues at **5** in the class Order. The numbers from **2** to **4** are defined in the class Client (see here after).

Position continues in another model class

```
public class Client {

    @DataField(pos = 2)
    private String clientNr;

    @DataField(pos = 3)
    private String firstName;

    @DataField(pos = 4)
    private String lastName;

}
```

case 2 : pattern

The pattern allows to enrich or validates the format of your data

Pattern

```

@CsvRecord(separator = ",")
public class Order {

    @DataField(pos = 1)
    private int orderNr;

    @DataField(pos = 5)
    private String isinCode;

    @DataField(name = "Name", pos = 6)
    private String instrumentName;

    @DataField(pos = 7, precision = 2)
    private BigDecimal amount;

    @DataField(pos = 8)
    private String currency;

    // pattern used during parsing or when the date is created
    @DataField(pos = 9, pattern = "dd-MM-yyyy")
    private Date orderDate;
}

```

case 3 : precision

The precision is helpful when you want to define the decimal part of your number.

Precision

```

@CsvRecord(separator = ",")
public class Order {

    @DataField(pos = 1)
    private int orderNr;

    @Link
    private Client client;

    @DataField(pos = 5)
    private String isinCode;

    @DataField(name = "Name", pos = 6)
    private String instrumentName;

    @DataField(pos = 7, precision = 2)
    private BigDecimal amount;

    @DataField(pos = 8)
    private String currency;
}

```

```

    @DataField(pos = 9, pattern = "dd-MM-yyyy")
    private Date orderDate;
}

```

case 4 : Position is different in output

The position attribute will inform bindy how to place the field in the CSV record generated. By default, the position used corresponds to the position defined with the attribute **pos**. If the position is different (that means that we have an asymmetric process comparing marshaling from unmarshaling) then we can use **position** to indicate this.

Here is an example:

Position is different in output

```

@DataRecord(separator = ",", isOrdered = true)
public class Order {

    // Positions of the fields start from 1 and not from 0

    @DataField(pos = 1, position = 11)
    private int orderNr;

    @DataField(pos = 2, position = 10)
    private String clientNr;

    @DataField(pos = 3, position = 9)
    private String firstName;

    @DataField(pos = 4, position = 8)
    private String lastName;

    @DataField(pos = 5, position = 7)
    private String instrumentCode;

    @DataField(pos = 6, position = 6)
    private String instrumentNumber;
}

```

This attribute of the annotation **@DataField** must be used in combination with attribute **isOrdered = true** of the annotation **@CsvRecord**.

case 5 : required

If a field is mandatory, simply use the attribute **required** set to true.

Required

```

@DataRecord(separator = ",")
public class Order {

    @DataField(pos = 1)
    private int orderNr;

    @DataField(pos = 2, required = true)
    private String clientNr;
}

```

```
@DataField(pos = 3, required = true)
private String firstName;

@DataField(pos = 4, required = true)
private String lastName;
}
```

If this field is not present in the record, then an error will be raised by the parser with the following information :

Some fields are missing (optional or mandatory), line :

case 6 : trim

If a field has leading and/or trailing spaces which should be removed before they are processed, simply use the attribute **trim** set to true.

Trim

```
@CsvRecord(separator = ",")
public class Order {

    @DataField(pos = 1, trim = true)
    private int orderNr;

    @DataField(pos = 2, trim = true)
    private Integer clientNr;

    @DataField(pos = 3, required = true)
    private String firstName;

    @DataField(pos = 4)
    private String lastName;
}
```

case 7 : defaultValue

If a field is not defined then uses the value indicated by the **defaultValue** attribute.

Default value

```
@CsvRecord(separator = ",")
public class Order {

    @DataField(pos = 1)
    private int orderNr;

    @DataField(pos = 2)
    private Integer clientNr;

    @DataField(pos = 3, required = true)
    private String firstName;
}
```

```

    @DataField(pos = 4, defaultValue = "Barin")
    private String lastName;
}

```

case 8 : columnName

Specifies the column name for the property only if **@CsvRecord** has annotation **generateHeaderColumns = true**.

Column Name

```

@CsvRecord(separator = ";", generateHeaderColumns = true)
public class Order {

    @DataField(pos = 1)
    private int orderNr;

    @DataField(pos = 5, columnName = "ISIN")
    private String isinCode;

    @DataField(name = "Name", pos = 6)
    private String instrumentName;
}

```

This attribute is only applicable to optional fields.

20.3.4. 4. FixedLengthRecord

The FixedLengthRecord annotation is used to identified the root class of the model. It represents a record = "a line of a file/message containing data fixed length (number of characters) formatted" and can be linked to several children model classes. This format is a bit particular because data of a field can be aligned to the right or to the left.

When the size of the data does not fill completely the length of the field, we can then add 'pad' characters.

Annotation name	Record type	Level
FixedLengthRecord	fixed	Class

Parameter name	Type	Required	Default value	Info
countGrapheme	boolean		false	Indicates how chars are counted

Parameter name	Type	Required	Default value	Info
crlf	String		WINDOWS	Character to be used to add a carriage return after each record (optional). Possible values: WINDOWS, UNIX, MAC, or custom. This option is used only during marshalling, whereas unmarshalling uses system default JDK provided line delimiter unless eol is customized.
eol	String			Character to be used to process considering end of line after each record while unmarshalling (optional – default: "", which help default JDK provided line delimiter to be used unless any other line delimiter provided) This option is used only during unmarshalling, where marshalling uses system default provided line delimiter as "WINDOWS" unless any other value is provided.
footer	Class		void	Indicates that the record(s) of this type may be followed by a single footer record at the end of the file
header	Class		void	Indicates that the record(s) of this type may be preceded by a single header record at the beginning of in the file
ignore Missing Chars	boolean		false	Indicates whether too short lines will be ignored
ignore Trailing Chars	boolean		false	Indicates that characters beyond the last mapped field can be ignored when unmarshalling / parsing. This annotation is associated to the root class of the model and must be declared one time.
length	int		0	The fixed length of the record (number of characters). It means that the record will always be that long padded with <code>\{#paddingChar()}'s</code>
name	String			Name describing the record (optional)
paddingChar	char			The char to pad with.
skipFooter	boolean		false	Configures the data format to skip marshalling / unmarshalling of the footer record. Configure this parameter on the primary record (e.g., not the header or footer).
skipHeader	boolean		false	Configures the data format to skip marshalling / unmarshalling of the header record. Configure this parameter on the primary record (e.g., not the header or footer).

A record may not be both a header/footer and a primary fixed-length record.

case 1 : Simple fixed length record

This simple example shows how to design the model to parse/format a fixed message

```
10A9PaulineMISINXD12345678BUYShare2500.45USD01-08-2009
```

Fixed-simple

```
@FixedLengthRecord(length=54, paddingChar=' ')
public static class Order {

    @DataField(pos = 1, length=2)
    private int orderNr;

    @DataField(pos = 3, length=2)
    private String clientNr;

    @DataField(pos = 5, length=7)
    private String firstName;

    @DataField(pos = 12, length=1, align="L")
    private String lastName;

    @DataField(pos = 13, length=4)
    private String instrumentCode;

    @DataField(pos = 17, length=10)
    private String instrumentNumber;

    @DataField(pos = 27, length=3)
    private String orderType;

    @DataField(pos = 30, length=5)
    private String instrumentType;

    @DataField(pos = 35, precision = 2, length=7)
    private BigDecimal amount;

    @DataField(pos = 42, length=3)
    private String currency;

    @DataField(pos = 45, length=10, pattern = "dd-MM-yyyy")
    private Date orderDate;
}
```

case 2 : Fixed length record with alignment and padding

This more elaborated example show how to define the alignment for a field and how to assign a padding character which is ' ' here:

```
10A9 PaulineM ISINXD12345678BUYShare2500.45USD01-08-2009
```

Fixed-padding-align

```
@FixedLengthRecord(length=60, paddingChar=' ')
```

```

public static class Order {

    @DataField(pos = 1, length=2)
    private int orderNr;

    @DataField(pos = 3, length=2)
    private String clientNr;

    @DataField(pos = 5, length=9)
    private String firstName;

    @DataField(pos = 14, length=5, align="L") // align text to the LEFT zone of the block
    private String lastName;

    @DataField(pos = 19, length=4)
    private String instrumentCode;

    @DataField(pos = 23, length=10)
    private String instrumentNumber;

    @DataField(pos = 33, length=3)
    private String orderType;

    @DataField(pos = 36, length=5)
    private String instrumentType;

    @DataField(pos = 41, precision = 2, length=7)
    private BigDecimal amount;

    @DataField(pos = 48, length=3)
    private String currency;

    @DataField(pos = 51, length=10, pattern = "dd-MM-yyyy")
    private Date orderDate;
}

```

case 3 : Field padding

Sometimes, the default padding defined for record cannot be applied to the field as we have a number format where we would like to pad with '0' instead of ' '. In this case, you can use in the model the attribute **paddingChar** on **@DataField** to set this value.

```
10A9 PaulineM ISINXD12345678BUYShare000002500.45USD01-08-2009
```

Fixed-padding-field

```

@FixedLengthRecord(length = 65, paddingChar = ' ')
public static class Order {

    @DataField(pos = 1, length = 2)
    private int orderNr;

    @DataField(pos = 3, length = 2)
    private String clientNr;

    @DataField(pos = 5, length = 9)

```

```

private String firstName;

@DataField(pos = 14, length = 5, align = "L")
private String lastName;

@DataField(pos = 19, length = 4)
private String instrumentCode;

@DataField(pos = 23, length = 10)
private String instrumentNumber;

@DataField(pos = 33, length = 3)
private String orderType;

@DataField(pos = 36, length = 5)
private String instrumentType;

@DataField(pos = 41, precision = 2, length = 12, paddingChar = '0')
private BigDecimal amount;

@DataField(pos = 53, length = 3)
private String currency;

@DataField(pos = 56, length = 10, pattern = "dd-MM-yyyy")
private Date orderDate;
}

```

case 4: Fixed length record with delimiter

Fixed-length records sometimes have delimited content within the record. The `firstName` and `lastName` fields are delimited with the `^` character in the following example:

```
10A9Pauline^M^ISINXD12345678BUYShare000002500.45USD01-08-2009
```

Fixed-delimited

```

@FixedLengthRecord
public static class Order {

    @DataField(pos = 1, length = 2)
    private int orderNr;

    @DataField(pos = 2, length = 2)
    private String clientNr;

    @DataField(pos = 3, delimiter = "^")
    private String firstName;

    @DataField(pos = 4, delimiter = "^")
    private String lastName;

    @DataField(pos = 5, length = 4)
    private String instrumentCode;

    @DataField(pos = 6, length = 10)

```

```

private String instrumentNumber;

@DataField(pos = 7, length = 3)
private String orderType;

@DataField(pos = 8, length = 5)
private String instrumentType;

@DataField(pos = 9, precision = 2, length = 12, paddingChar = '0')
private BigDecimal amount;

@DataField(pos = 10, length = 3)
private String currency;

@DataField(pos = 11, length = 10, pattern = "dd-MM-yyyy")
private Date orderDate;
}

```

The **pos** value(s) in a fixed-length record may optionally be defined using ordinal, sequential values instead of precise column numbers.

case 5 : Fixed length record with record-defined field length

Occasionally a fixed-length record may contain a field that define the expected length of another field within the same record. In the following example the length of the **instrumentNumber** field value is defined by the value of **instrumentNumberLen** field in the record.

```
10A9Pauline^M^ISIN10XD12345678BUYShare000002500.45USD01-08-2009
```

Fixed-delimited

```

@FixedLengthRecord
public static class Order {

    @DataField(pos = 1, length = 2)
    private int orderNr;

    @DataField(pos = 2, length = 2)
    private String clientNr;

    @DataField(pos = 3, delimiter = "^")
    private String firstName;

    @DataField(pos = 4, delimiter = "^")
    private String lastName;

    @DataField(pos = 5, length = 4)
    private String instrumentCode;

    @DataField(pos = 6, length = 2, align = "R", paddingChar = '0')
    private int instrumentNumberLen;

    @DataField(pos = 7, lengthPos=6)
    private String instrumentNumber;
}

```

```

@DataField(pos = 8, length = 3)
private String orderType;

@DataField(pos = 9, length = 5)
private String instrumentType;

@DataField(pos = 10, precision = 2, length = 12, paddingChar = '0')
private BigDecimal amount;

@DataField(pos = 11, length = 3)
private String currency;

@DataField(pos = 12, length = 10, pattern = "dd-MM-yyyy")
private Date orderDate;
}

```

case 6 : Fixed length record with header and footer

Bindy will discover fixed-length header and footer records that are configured as part of the model – provided that the annotated classes exist either in the same package as the primary **@FixedLengthRecord** class, or within one of the configured scan packages. The following text illustrates two fixed-length records that are bracketed by a header record and footer record.

```

101-08-2009
10A9 PaulineM ISINXD12345678BUYShare000002500.45USD01-08-2009
10A9 RichN ISINXD12345678BUYShare000002700.45USD01-08-2009
90000000002

```

Fixed-header-and-footer-main-class

```

@FixedLengthRecord(header = OrderHeader.class, footer = OrderFooter.class)
public class Order {

    @DataField(pos = 1, length = 2)
    private int orderNr;

    @DataField(pos = 2, length = 2)
    private String clientNr;

    @DataField(pos = 3, length = 9)
    private String firstName;

    @DataField(pos = 4, length = 5, align = "L")
    private String lastName;

    @DataField(pos = 5, length = 4)
    private String instrumentCode;

    @DataField(pos = 6, length = 10)
    private String instrumentNumber;

    @DataField(pos = 7, length = 3)
    private String orderType;

    @DataField(pos = 8, length = 5)
    private String instrumentType;
}

```

```

@DataField(pos = 9, precision = 2, length = 12, paddingChar = '0')
private BigDecimal amount;

@DataField(pos = 10, length = 3)
private String currency;

@DataField(pos = 11, length = 10, pattern = "dd-MM-yyyy")
private Date orderDate;
}

@FixedLengthRecord
public class OrderHeader {
    @DataField(pos = 1, length = 1)
    private int recordType = 1;

    @DataField(pos = 2, length = 10, pattern = "dd-MM-yyyy")
    private Date recordDate;
}

@FixedLengthRecord
public class OrderFooter {

    @DataField(pos = 1, length = 1)
    private int recordType = 9;

    @DataField(pos = 2, length = 9, align = "R", paddingChar = '0')
    private int numberOfRecordsInTheFile;
}

```

case 7 : Skipping content when parsing a fixed length record

It is common to integrate with systems that provide fixed-length records containing more information than needed for the target use case. It is useful in this situation to skip the declaration and parsing of those fields that we do not need. To accomodate this, Bindy will skip forward to the next mapped field within a record if the **pos** value of the next declared field is beyond the cursor position of the last parsed field. Using absolute **pos** locations for the fields of interest (instead of ordinal values) causes Bindy to skip content between two fields.

Similarly, it is possible that none of the content beyond some field is of interest. In this case, you can tell Bindy to skip parsing of everything beyond the last mapped field by setting the **ignoreTrailingChars** property on the **@FixedLengthRecord** declaration.

```

@FixedLengthRecord(ignoreTrailingChars = true)
public static class Order {

    @DataField(pos = 1, length = 2)
    private int orderNr;

    @DataField(pos = 3, length = 2)
    private String clientNr;

    // any characters that appear beyond the last mapped field will be ignored
}

```

20.3.5. 5. Message

The Message annotation is used to identify the class of your model who will contain key value pairs fields. This kind of format is used mainly in Financial Exchange Protocol Messages (FIX). Nevertheless, this annotation can be used for any other format where data are identified by keys. The key pair values are separated each other by a separator which can be a special character like a tab delimiter (unicode representation : `\u0009`) or a start of heading (unicode representation : `\u0001`)

NOTE

To work with FIX messages, the model must contain a Header and Trailer classes linked to the root message class which could be a Order class. This is not mandatory but will be very helpful when you will use camel-bindy in combination with camel-fix which is a Fix gateway based on quickFix project .

Annotation name	Record type	Level
Message	key value pair	Class

Parameter name	Type	Required	Default value	Info
keyValuePairSeparator	String	✓		Key value pair separator is used to split the values from their keys (mandatory). Can be <code>'\u0001'</code> , <code>'\u0009'</code> , <code>'#'</code> , or <code>'anything'</code> .
pairSeparator	String	✓		Pair separator used to split the key value pairs in tokens (mandatory). Can be <code>'='</code> , <code>','</code> , or <code>'anything'</code> .
crlf	String		WINDOWS	Character to be used to add a carriage return after each record (optional). Possible values = WINDOWS, UNIX, MAC, or custom. If you specify a value other than the three listed before, the value you enter (custom) will be used as the CRLF character(s).
isOrdered	boolean		false	Indicates if the message must be ordered in output. This annotation is associated to the message class of the model and must be declared one time.
name	String			Name describing the message (optional)
type	String		FIX	type is used to define the type of the message (e.g. FIX, EMX, ...) (optional)
version	String		4.1	version defines the version of the message (e.g. 4.1, ...) (optional)

case 1 : separator = `'\u0001'`

The separator used to segregate the key value pair fields in a FIX message is the ASCII **01** character or in unicode format **\u0001**. This character must be escaped a second time to avoid a java runtime error. Here is an example :

```
8=FIX.4.1 9=20 34=1 35=0 49=INVMGR 56=BRKR 1=BE.CHM.001 11=CHM0001-01 22=4 ...
```

and how to use the annotation:

FIX - message

```
@Message(keyValuePairSeparator = "=", pairSeparator = "\u0001", type="FIX", version="4.1")
public class Order {

}
```

Look at test cases

The ASCII character like tab, ... cannot be displayed in WIKI page. So, have a look to the test case of camel-bindy to see exactly how the FIX message looks like (<https://github.com/apache/camel/blob/main/components/camel-bindy/src/test/data/fix/fix.txt>) and the Order, Trailer, Header classes (<https://github.com/apache/camel/blob/main/components/camel-bindy/src/test/java/org/apache/camel/dataformat/bindy/model/fix/simple/Order.java>).

20.3.6. 6. KeyValuePairField

The KeyValuePairField annotation defines the property of a key value pair field. Each KeyValuePairField is identified by a tag (= key) and its value associated, a type (string, int, date, ...), optionally a pattern and if the field is required.

Annotation name	Record type	Level
KeyValuePairField	Key Value Pair - FIX	Property

Parameter name	Type	Required	Default value	Info
tag	int	✓		tag identifying the field in the message (mandatory) - must be unique
impliedDecimalSeparator	boolean		false	Camel 2.11: Indicates if there is a decimal point implied at a specified location
name	String			name of the field (optional)

Parameter name	Type	Required	Default value	Info
pattern	String			pattern that the formatter will use to transform the data (optional)
position	int		0	Position of the field in the message generated - must be used when the position of the key/tag in the FIX message must be different
precision	int		0	precision of the BigDecimal number to be created
required	boolean		false	Indicates if the field is mandatory
timezone	String			Timezone to be used.

case 1: tag

This parameter represents the key of the field in the message:

FIX message - Tag

```

@Message(keyValuePairSeparator = "=", pairSeparator = "\u0001", type="FIX", version="4.1")
public class Order {

    @Link Header header;

    @Link Trailer trailer;

    @KeyValuePairField(tag = 1) // Client reference
    private String Account;

    @KeyValuePairField(tag = 11) // Order reference
    private String ClOrdId;

    @KeyValuePairField(tag = 22) // Fund ID type (Sedol, ISIN, ...)
    private String IDSource;

    @KeyValuePairField(tag = 48) // Fund code
    private String SecurityId;

    @KeyValuePairField(tag = 54) // Movement type ( 1 = Buy, 2 = sell)
    private String Side;

    @KeyValuePairField(tag = 58) // Free text
    private String Text;
}

```

case 2 : Different position in output

If the tags/keys that we will put in the FIX message must be sorted according to a predefined order, then use the attribute **position** of the annotation **@KeyValuePairField**.

FIX message - Tag - sort

```
@Message(keyValuePairSeparator = "=", pairSeparator = "\\u0001", type = "FIX", version = "4.1",
isOrdered = true)
public class Order {

    @Link Header header;

    @Link Trailer trailer;

    @KeyValuePairField(tag = 1, position = 1) // Client reference
    private String account;

    @KeyValuePairField(tag = 11, position = 3) // Order reference
    private String clOrdId;
}
```

20.3.7. 7. Section

In FIX message of fixed length records, it is common to have different sections in the representation of the information : header, body and section. The purpose of the annotation **@Section** is to inform bindy about which class of the model represents the header (= section 1), body (= section 2) and footer (= section 3)

Only one attribute/parameter exists for this annotation.

Annotation name	Record type	Level
Section	FIX	Class

Parameter name	Type	Required	Default value	Info
number	int	✓		Number of the section

case 1 : Section

Definition of the header section:

FIX message - Section - Header

```
@Section(number = 1)
public class Header {
```

```

@KeyValuePairField(tag = 8, position = 1) // Message Header
private String beginString;

@KeyValuePairField(tag = 9, position = 2) // Checksum
private int bodyLength;
}

```

Definition of the body section:

FIX message - Section - Body

```

@section(number = 2)
@Message(keyValuePairSeparator = "=", pairSeparator = "\\u0001", type = "FIX", version = "4.1",
isOrdered = true)
public class Order {

    @Link Header header;

    @Link Trailer trailer;

    @KeyValuePairField(tag = 1, position = 1) // Client reference
    private String account;

    @KeyValuePairField(tag = 11, position = 3) // Order reference
    private String clOrdId;
}

```

Definition of the footer section:

FIX message - Section - Footer

```

@section(number = 3)
public class Trailer {

    @KeyValuePairField(tag = 10, position = 1)
    // CheckSum
    private int checkSum;

    public int getCheckSum() {
        return checkSum;
    }
}

```

20.3.8. 8. OneToMany

The purpose of the annotation **@OneToMany** is to allow to work with a **List<?>** field defined a POJO class or from a record containing repetitive groups.

NOTE

Restrictions for OneToMany

Be careful, the one to many of bindy does not allow to handle repetitions defined on several levels of the hierarchy.

The relation OneToMany ONLY WORKS in the following cases :

- Reading a FIX message containing repetitive groups (= group of tags/keys)
- Generating a CSV with repetitive data

Annotation name	Record type	Level
OneToMany	all	Property

Parameter name	Type	Required	Default value	Info
mappedTo	String			Class name associated to the type of the List<Type of the Class>

case 1: Generating CSV with repetitive data

Here is the CSV output that we want :

```
Claus,Ibsen,Camel in Action 1,2010,35
Claus,Ibsen,Camel in Action 2,2012,35
Claus,Ibsen,Camel in Action 3,2013,35
Claus,Ibsen,Camel in Action 4,2014,35
```

NOTE

The repetitive data concern the title of the book and its publication date while first, last name and age are common and the classes used to modeling this. The Author class contains a List of Book.

Generate CSV with repetitive data

```
@CsvRecord(separator=",")
public class Author {

    @DataField(pos = 1)
    private String firstName;

    @DataField(pos = 2)
    private String lastName;

    @OneToMany
    private List<Book> books;

    @DataField(pos = 5)
    private String Age;
}

public class Book {
```

```

    @DataField(pos = 3)
    private String title;

    @DataField(pos = 4)
    private String year;
}

```

case 2 : Reading FIX message containing group of tags/keys

Here is the message that we would like to process in our model :

```

8=FIX 4.19=2034=135=049=INVMGR56=BRKR
1=BE.CHM.00111=CHM0001-0158=this is a camel - bindy test
22=448=BE000124567854=1
22=548=BE000987654354=2
22=648=BE000999999954=3
10=220

```

Tags 22, 48 and 54 are repeated.

And the code:

Reading FIX message containing group of tags/keys

```

public class Order {

    @Link Header header;

    @Link Trailer trailer;

    @KeyValuePairField(tag = 1) // Client reference
    private String account;

    @KeyValuePairField(tag = 11) // Order reference
    private String clOrdId;

    @KeyValuePairField(tag = 58) // Free text
    private String text;

    @OneToMany(mappedTo =
"org.apache.camel.dataformat.bindy.model.fix.complex.onetomany.Security")
    List<Security> securities;
}

public class Security {

    @KeyValuePairField(tag = 22) // Fund ID type (Sedol, ISIN, ...)
    private String idSource;

    @KeyValuePairField(tag = 48) // Fund code
    private String securityCode;

    @KeyValuePairField(tag = 54) // Movement type ( 1 = Buy, 2 = sell)
    private String side;
}

```

20.3.9. 9. BindyConverter

The purpose of the annotation **@BindyConverter** is define a converter to be used on field level. The provided class must implement the `Format` interface.

```
@FixedLengthRecord(length = 10, paddingChar = ' ')
public static class DataModel {
    @DataField(pos = 1, length = 10, trim = true)
    @BindyConverter(CustomConverter.class)
    public String field1;
}

public static class CustomConverter implements Format<String> {
    @Override
    public String format(String object) throws Exception {
        return (new StringBuilder(object)).reverse().toString();
    }

    @Override
    public String parse(String string) throws Exception {
        return (new StringBuilder(string)).reverse().toString();
    }
}
```

20.3.10. 10. FormatFactories

The purpose of the annotation **@FormatFactories** is to define a set of converters at record-level. The provided classes must implement the **FormatFactoryInterface** interface.

```
@CsvRecord(separator = ",")
@FormatFactories({OrderNumberFormatFactory.class})
public static class Order {

    @DataField(pos = 1)
    private OrderNumber orderNr;

    @DataField(pos = 2)
    private String firstName;
}

public static class OrderNumber {
    private int orderNr;

    public static OrderNumber ofString(String orderNumber) {
        OrderNumber result = new OrderNumber();
        result.orderNr = Integer.valueOf(orderNumber);
        return result;
    }
}

public static class OrderNumberFormatFactory extends AbstractFormatFactory {

    {
        supportedClasses.add(OrderNumber.class);
    }
}
```

```

@Override
public Format<?> build(FormattingOptions formattingOptions) {
    return new Format<OrderNumber>() {
        @Override
        public String format(OrderNumber object) throws Exception {
            return String.valueOf(object.orderNr);
        }

        @Override
        public OrderNumber parse(String string) throws Exception {
            return OrderNumber.ofString(string);
        }
    };
}
}

```

20.4. SUPPORTED DATATYPES

The DefaultFormatFactory makes formatting of the following datatype available by returning an instance of the interface FormatFactoryInterface based on the provided FormattingOptions:

- BigDecimal
- BigInteger
- Boolean
- Byte
- Character
- Date
- Double
- Enums
- Float
- Integer
- LocalDate
- LocalDateTime
- LocalTime
- Long
- Short
- String

The DefaultFormatFactory can be overridden by providing an instance of FactoryRegistry in the registry in use (e.g. spring or JNDI).

20.5. USING THE JAVA DSL

The next step instantiates the DataFormat *bindy* class associated with this record type and providing a class as a parameter.

For example the following uses the class **BindyCsvDataFormat** (which corresponds to the class associated with the CSV record type) which is configured with *com.acme.model.MyModel.class* to initialize the model objects configured in this package.

```
DataFormat bindy = new BindyCsvDataFormat(com.acme.model.MyModel.class);
```

20.5.1. Setting locale

Bindy supports configuring the locale on the dataformat, such as

```
BindyCsvDataFormat bindy = new BindyCsvDataFormat(com.acme.model.MyModel.class);

bindy.setLocale("us");
```

Or to use the platform default locale then use "default" as the locale name.

```
BindyCsvDataFormat bindy = new BindyCsvDataFormat(com.acme.model.MyModel.class);

bindy.setLocale("default");
```

20.5.2. Unmarshaling

```
from("file://inbox")
  .unmarshal(bindy)
  .to("direct:handleOrders");
```

Alternatively, you can use a named reference to a data format which can then be defined in your Registry e.g. your Spring XML file:

```
from("file://inbox")
  .unmarshal("myBindyDataFormat")
  .to("direct:handleOrders");
```

The Camel route will pick-up files in the inbox directory, unmarshall CSV records into a collection of model objects and send the collection to the route referenced by **handleOrders**.

The collection returned is a **List of Map** objects. Each Map within the list contains the model objects that were marshalled out of each line of the CSV. The reason behind this is that *each line can correspond to more than one object*. This can be confusing when you simply expect one object to be returned per line.

Each object can be retrieve using its class name.

```
List<Map<String, Object>> unmarshaledModels = (List<Map<String, Object>>)
exchange.getIn().getBody();

int modelCount = 0;
```

```

for (Map<String, Object> model : unmarshaledModels) {
    for (String className : model.keySet()) {
        Object obj = model.get(className);
        LOG.info("Count : " + modelCount + ", " + obj.toString());
    }
    modelCount++;
}

LOG.info("Total CSV records received by the csv bean : " + modelCount);

```

Assuming that you want to extract a single Order object from this map for processing in a route, you could use a combination of a Splitter and a Processor as per the following:

```

from("file://inbox")
    .unmarshal(bindy)
    .split(body())
    .process(new Processor() {
        public void process(Exchange exchange) throws Exception {
            Message in = exchange.getIn();
            Map<String, Object> modelMap = (Map<String, Object>) in.getBody();
            in.setBody(modelMap.get(Order.class.getCanonicalName()));
        }
    })
    .to("direct:handleSingleOrder")
    .end();

```

Take care of the fact that Bindy uses CHARSET_NAME property or the CHARSET_NAME header as define in the Exchange interface to do a charset conversion of the inputstream received for unmarshalling. In some producers (e.g. file-endpoint) you can define a charset. The charset conversion can already been done by this producer. Sometimes you need to remove this property or header from the exchange before sending it to the unmarshal. If you don't remove it the conversion might be done twice which might lead to unwanted results.

```

from("file://inbox?charset=Cp922")
    .removeProperty(Exchange.CHARSET_NAME)
    .unmarshal("myBindyDataFormat")
    .to("direct:handleOrders");

```

20.5.3. Marshaling

To generate CSV records from a collection of model objects, you create the following route :

```

from("direct:handleOrders")
    .marshal(bindy)
    .to("file://outbox")

```

20.6. USING SPRING XML

This is really easy to use Spring as your favorite DSL language to declare the routes to be used for camel-bindy. The following example shows two routes where the first will pick-up records from files, unmarshal the content and bind it to their model. The result is then send to a pojo (doing nothing special) and place them into a queue.

The second route will extract the pojos from the queue and marshal the content to generate a file containing the CSV record.

Spring DSL

```
<?xml version="1.0" encoding="UTF-8"?>

<beans xmlns="http://www.springframework.org/schema/beans"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="
    http://www.springframework.org/schema/beans
    http://www.springframework.org/schema/beans/spring-beans.xsd
    http://camel.apache.org/schema/spring
    http://camel.apache.org/schema/spring/camel-spring.xsd">

  <!-- Queuing engine - ActiveMq - work locally in mode virtual memory -->
  <bean id="activemq" class="org.apache.activemq.camel.component.ActiveMQComponent">
    <property name="brokerURL" value="vm://localhost:61616"/>
  </bean>

  <camelContext xmlns="http://camel.apache.org/schema/spring">
    <dataFormats>
      <bindy id="bindyDataformat" type="Csv" classType="org.apache.camel.bindy.model.Order"/>
    </dataFormats>

    <route>
      <from uri="file://src/data/csv/?noop=true" />
      <unmarshal ref="bindyDataformat" />
      <to uri="bean:csv" />
      <to uri="activemq:queue:in" />
    </route>

    <route>
      <from uri="activemq:queue:in" />
      <marshal ref="bindyDataformat" />
      <to uri="file://src/data/csv/out/" />
    </route>
  </camelContext>
</beans>
```

NOTE

Please verify that your model classes implements serializable otherwise the queue manager will raise an error.

20.7. DEPENDENCIES

To use Bindy in your camel routes you need to add the a dependency on **camel-bindy** which implements this data format.

If you use maven you could just add the following to your pom.xml, substituting the version number for the latest & greatest release (see the download page for the latest versions).

```
<dependency>
  <groupId>org.apache.camel</groupId>
```

```

<artifactId>camel-bindy</artifactId>
<version>{CamelSBVersion}</version>
</dependency>

```

20.8. SPRING BOOT AUTO-CONFIGURATION

The component supports 18 options, which are listed below.

Name	Description	Default	Type
<code>camel.dataformat.bindy-csv.allow-empty-stream</code>	Whether to allow empty streams in the unmarshal process. If true, no exception will be thrown when a body without records is provided.	false	Boolean
<code>camel.dataformat.bindy-csv.class-type</code>	Name of model class to use.		String
<code>camel.dataformat.bindy-csv.enabled</code>	Whether to enable auto configuration of the bindy-csv data format. This is enabled by default.		Boolean
<code>camel.dataformat.bindy-csv.locale</code>	To configure a default locale to use, such as us for united states. To use the JVM platform default locale then use the name default.		String
<code>camel.dataformat.bindy-csv.type</code>	Whether to use Csv, Fixed, or KeyValue.		String
<code>camel.dataformat.bindy-csv.unwrap-single-instance</code>	When unmarshalling should a single instance be unwrapped and returned instead of wrapped in a <code>java.util.List</code> .	true	Boolean
<code>camel.dataformat.bindy-fixed.allow-empty-stream</code>	Whether to allow empty streams in the unmarshal process. If true, no exception will be thrown when a body without records is provided.	false	Boolean
<code>camel.dataformat.bindy-fixed.class-type</code>	Name of model class to use.		String
<code>camel.dataformat.bindy-fixed.enabled</code>	Whether to enable auto configuration of the bindy-fixed data format. This is enabled by default.		Boolean

Name	Description	Default	Type
<code>camel.dataformat.bindy-fixed.locale</code>	To configure a default locale to use, such as us for united states. To use the JVM platform default locale then use the name default.		String
<code>camel.dataformat.bindy-fixed.type</code>	Whether to use Csv, Fixed, or KeyValue.		String
<code>camel.dataformat.bindy-fixed.unwrap-single-instance</code>	When unmarshalling should a single instance be unwrapped and returned instead of wrapped in a <code>java.util.List</code> .	true	Boolean
<code>camel.dataformat.bindy-kvp.allow-empty-stream</code>	Whether to allow empty streams in the unmarshal process. If true, no exception will be thrown when a body without records is provided.	false	Boolean
<code>camel.dataformat.bindy-kvp.class-type</code>	Name of model class to use.		String
<code>camel.dataformat.bindy-kvp.enabled</code>	Whether to enable auto configuration of the bindy-kvp data format. This is enabled by default.		Boolean
<code>camel.dataformat.bindy-kvp.locale</code>	To configure a default locale to use, such as us for united states. To use the JVM platform default locale then use the name default.		String
<code>camel.dataformat.bindy-kvp.type</code>	Whether to use Csv, Fixed, or KeyValue.		String
<code>camel.dataformat.bindy-kvp.unwrap-single-instance</code>	When unmarshalling should a single instance be unwrapped and returned instead of wrapped in a <code>java.util.List</code> .	true	Boolean

CHAPTER 21. BROWSE

Both producer and consumer are supported

The Browse component provides a simple `BrowsableEndpoint` which can be useful for testing, visualisation tools or debugging. The exchanges sent to the endpoint are all available to be browsed.

21.1. DEPENDENCIES

When using **browse** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-browse-starter</artifactId>
</dependency>
```

21.2. URI FORMAT

```
browse:someName[?options]
```

Where **someName** can be any string to uniquely identify the endpoint.

21.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

21.3.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).
- directly in the Java code.

21.3.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

21.4. COMPONENT OPTIONS

The Browse component supports 3 options, which are listed below.

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

21.5. ENDPOINT OPTIONS

The Browse endpoint is configured using URI syntax:

```
browse:name
```

with the following path and query parameters:

21.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
name (common)	Required A name which can be any string to uniquely identify the endpoint.		String

21.5.2. Query Parameters (4 parameters)

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer (advanced))	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		<code>ExceptionHandler</code>
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • <code>InOnly</code> • <code>InOut</code> • <code>InOptionalOut</code>		<code>ExchangePattern</code>

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

21.6. SAMPLE

In the route below, we insert a **browse:** component to be able to browse the Exchanges that are passing through:

```
from("activemq:order.in").to("browse:orderReceived").to("bean:processOrder");
```

We can now inspect the received exchanges from within the Java code:

```
private CamelContext context;

public void inspectReceivedOrders() {
    BrowseableEndpoint browse = context.getEndpoint("browse:orderReceived",
BrowseableEndpoint.class);
    List<Exchange> exchanges = browse.getExchanges();

    // then we can inspect the list of received exchanges from Java
    for (Exchange exchange : exchanges) {
        String payload = exchange.getIn().getBody();
        // do something with payload
    }
}
```

21.7. SPRING BOOT AUTO-CONFIGURATION

The component supports 4 options, which are listed below.

Name	Description	Default	Type
------	-------------	---------	------

Name	Description	Default	Type
camel.component.browse.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.browse.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.browse.enabled	Whether to enable auto configuration of the browse component. This is enabled by default.		Boolean
camel.component.browse.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 22. CASSANDRA CQL

Both producer and consumer are supported

[Apache Cassandra](#) is an open source NoSQL database designed to handle large amounts on commodity hardware. Like Amazon's DynamoDB, Cassandra has a peer-to-peer and master-less architecture to avoid single point of failure and garanty high availability. Like Google's BigTable, Cassandra data is structured using column families which can be accessed through the Thrift RPC API or a SQL-like API called CQL.

NOTE

This component aims at integrating Cassandra 2.0+ using the CQL3 API (not the Thrift API). It's based on [Cassandra Java Driver](#) provided by DataStax.

22.1. DEPENDENCIES

When using **cql** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-cassandraql-starter</artifactId>
</dependency>
```

22.2. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

22.2.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).
- directly in the Java code.

22.2.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

22.3. COMPONENT OPTIONS

The Cassandra CQL component supports 3 options, which are listed below.

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

Name	Description	Default	Type
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

22.4. ENDPOINT OPTIONS

The Cassandra CQL endpoint is configured using URI syntax:

```
cql:beanRef:hosts:port/keyspace
```

with the following path and query parameters:

22.4.1. Path Parameters (4 parameters)

Name	Description	Default	Type
beanRef (common)	beanRef is defined using bean:id.		String
hosts (common)	Hostname(s) Cassandra server(s). Multiple hosts can be separated by comma.		String
port (common)	Port number of Cassandra server(s).		Integer
keyspace (common)	Keyspace to use.		String

22.4.2. Query Parameters (30 parameters)

Name	Description	Default	Type
clusterName (common)	Cluster name.		String

Name	Description	Default	Type
consistencyLevel (common)	Consistency level to use. Enum values: • ANY • ONE • TWO • THREE • QUORUM • ALL • LOCAL_ONE • LOCAL_QUORUM • EACH_QUORUM • SERIAL • LOCAL_SERIAL		DefaultConsistencyLevel
cql (common)	CQL query to perform. Can be overridden with the message header with key CamelCqlQuery.		String
datacenter (common)	Datacenter to use.	datacenter1	String
loadBalancingPolicyClass (common)	To use a specific LoadBalancingPolicyClass.		String
password (common)	Password for session authentication.		String
prepareStatements (common)	Whether to use PreparedStatements or regular Statements.	true	boolean
resultSetConversionStrategy (common)	To use a custom class that implements logic for converting ResultSet into message body ALL, ONE, LIMIT_10, LIMIT_100...		ResultSetConversionStrategy
session (common)	To use the Session instance (you would normally not use this option).		CqlSession
username (common)	Username for session authentication.		String

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean
exceptionHandler (consumer (advanced))	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		<code>ExceptionHandler</code>
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: ● <code>InOnly</code> ● <code>InOut</code> ● <code>InOptionalOut</code>		<code>ExchangePattern</code>
pollStrategy (consumer (advanced))	A pluggable <code>org.apache.camel.PollingConsumerPollingStrategy</code> allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		<code>PollingConsumerPollStrategy</code>

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.		int
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.		int
delay (scheduler)	Milliseconds before the next poll.	500	long
greedy (scheduler)	If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts.	1000	long
repeatCount (scheduler)	Specifies a maximum limit of number of fires. So if you set it to 1, the scheduler will only fire once. If you set it to 5, it will only fire five times. A value of zero or negative means fire forever.	0	long

Name	Description	Default	Type
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that. Enum values: • TRACE • DEBUG • INFO • WARN • ERROR • OFF	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz component. Use value spring or quartz for built in scheduler.	none	Object
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for initialDelay and delay options. Enum values: • NANOSECONDS • MICROSECONDS • MILLISECONDS • SECONDS • MINUTES • HOURS • DAYS	MILLIS ECON DS	TimeUnit

Name	Description	Default	Type
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See <code>ScheduledExecutorService</code> in JDK for details.	true	boolean

22.5. ENDPOINT CONNECTION SYNTAX

The endpoint can initiate the Cassandra connection or use an existing one.

URI	Description
cql:localhost/keyspace	Single host, default port, usual for testing
cql:host1,host2/keyspace	Multi host, default port
cql:host1,host2:9042/keyspace	Multi host, custom port
cql:host1,host2	Default port and keyspace
cql:bean:sessionRef	Provided Session reference
cql:bean:clusterRef/keyspace	Provided Cluster reference

To fine tune the Cassandra connection (SSL options, pooling options, load balancing policy, retry policy, reconnection policy...), create your own Cluster instance and give it to the Camel endpoint.

22.6. MESSAGES

22.6.1. Incoming Message

The Camel Cassandra endpoint expects a bunch of simple objects (**Object** or **Object[]** or **Collection<Object>**) which will be bound to the CQL statement as query parameters. If message body is null or empty, then CQL query will be executed without binding parameters.

Headers

- **CamelCqlQuery** (optional, **String** or **RegularStatement**)
CQL query either as a plain String or built using the **QueryBuilder**.

22.6.2. Outgoing Message

The Camel Cassandra endpoint produces one or many a Cassandra Row objects depending on the **resultSetConversionStrategy**:

- **List<Row>** if **resultSetConversionStrategy** is **ALL** or **LIMIT_[0-9]+**
- **Single`Row`** if **resultSetConversionStrategy** is **ONE**

- Anything else, if **resultSetConversionStrategy** is a custom implementation of the **ResultSetConversionStrategy**

22.7. REPOSITORIES

Cassandra can be used to store message keys or messages for the idempotent and aggregation EIP.

Cassandra might not be the best tool for queuing use cases yet, read [Cassandra anti-patterns queues and queue like datasets](#). It's advised to use LeveledCompaction and a small GC grace setting for these tables to allow tombstoned rows to be removed quickly.

22.8. IDEMPOTENT REPOSITORY

The **NamedCassandraIdempotentRepository** stores messages keys in a Cassandra table like this:

CAMEL_IDEMPOTENT.cql

```
CREATE TABLE CAMEL_IDEMPOTENT (
  NAME varchar, -- Repository name
  KEY varchar, -- Message key
  PRIMARY KEY (NAME, KEY)
) WITH compaction = {'class':'LeveledCompactionStrategy'}
AND gc_grace_seconds = 86400;
```

This repository implementation uses lightweight transactions (also known as Compare and Set) and requires Cassandra 2.0.7+.

Alternatively, the **CassandraIdempotentRepository** does not have a **NAME** column and can be extended to use a different data model.

Option	Default	Description
table	CAMEL_IDEMPOTENT	Table name
pkColumns	NAME, `KEY`	Primary key columns
name		Repository name, value used for NAME column
ttl		Key time to live
writeConsistencyLevel		Consistency level used to insert/delete key: ANY, ONE, TWO, QUORUM, LOCAL_QUORUM...
readConsistencyLevel		Consistency level used to read/check key: ONE, TWO, QUORUM, LOCAL_QUORUM...

22.9. AGGREGATION REPOSITORY

The **NamedCassandraAggregationRepository** stores exchanges by correlation key in a Cassandra table like this:

CAMEL_AGGREGATION.cql

```
CREATE TABLE CAMEL_AGGREGATION (
  NAME varchar,      -- Repository name
  KEY varchar,       -- Correlation id
  EXCHANGE_ID varchar, -- Exchange id
  EXCHANGE blob,     -- Serialized exchange
  PRIMARY KEY (NAME, KEY)
) WITH compaction = {'class':'LeveledCompactionStrategy'}
AND gc_grace_seconds = 86400;
```

Alternatively, the **CassandraAggregationRepository** does not have a **NAME** column and can be extended to use a different data model.

Option	Default	Description
table	CAMEL_AGGREGATION	Table name
pkColumns	NAME,KEY	Primary key columns
exchangeIdColumn	EXCHANGE_ID	Exchange Id column
exchangeColumn	EXCHANGE	Exchange content column
name		Repository name, value used for NAME column
ttl		Exchange time to live
writeConsistencyLevel		Consistency level used to insert/delete exchange: ANY, ONE, TWO, QUORUM, LOCAL_QUORUM...
readConsistencyLevel		Consistency level used to read/check exchange: ONE, TWO, QUORUM, LOCAL_QUORUM...

22.10. EXAMPLES

To insert something on a table you can use the following code:

```
String CQL = "insert into camel_user(login, first_name, last_name) values (?, ?, ?);
from(\"direct:input\")
```

```
.to("cql://localhost/camel_ks?cql=" + CQL);
```

At this point you should be able to insert data by using a list as body

```
Arrays.asList("davsclaus", "Claus", "Ibsen")
```

The same approach can be used for updating or querying the table.

22.11. SPRING BOOT AUTO-CONFIGURATION

The component supports 4 options, which are listed below.

Name	Description	Default	Type
camel.component.cql.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.cql.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.cql.enabled	Whether to enable auto configuration of the cql component. This is enabled by default.		Boolean
camel.component.cql.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 23. CICS

Since Camel 4.4-redhat

Only producer is supported.

This component allows you to interact with the IBM [CICS®](#) general-purpose transaction processing subsystem.

NOTE

Only synchronous mode call are supported.

23.1. DEPENDENCIES

When using **camel-cics** with Red Hat build of Camel Spring Boot, add the following Maven dependency to your **pom.xml** to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-cics-starter</artifactId>
</dependency>
```

You must also declare the **ctgclient.jar** dependency when working with **camel-cics** starter.

```
<dependency>
  <artifactId>com.ibm</artifactId>
  <groupId>ctgclient</groupId>
  <scope>system</scope>
  <systemPath>${basedir}/lib/ctgclient.jar</systemPath>
</dependency>
```

This JAR is provided by IBM and is included in the **cics** system.

23.2. URI FORMAT

```
cics://[interfaceType]/[dataExchangeType][?options]
```

Where **interfaceType** is the CICS set of the external API that the **camel-cics** invokes. At the moment, only ECI (External Call Interface) is supported. This component communicates with the CICS server using two kinds of **dataExchangeType**.

- **commarea** is a block of storage, limited to 32763 bytes, allocated by the program.
- **channel** is the new mechanism for exchanging data, analogous to a parameter list.

By default, if **dataExchangeType** is not specified, this component uses **commarea**:

```
cics://eci?host=xxx&port=xxx...
```

To use the **channel** and the container you must specify it explicitly in the URI

```
cics://eci/channel?host=xxx&port=xxx...
```

23.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

23.3.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).
- directly in the Java code.

23.3.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

23.4. COMPONENT OPTIONS

The CICS component supports 17 options, which are listed below.

Name	Description	Default	Type
ctgDebug	Enable debug mode on the underlying IBM CGT client.	false	java.lang.Boolean
eciBinding	The Binding instance to transform a Camel Exchange to EciRequest and vice versa		com.redhat.camel.component.cics.CICSEciBinding
eciTimeout	The ECI timeout value associated with this ECIRequest object. An ECI timeout value of zero indicates that this ECIRequest will not be timed out by CICS Transaction Gateway. An ECI timeout value greater than zero indicates that the ECIRequest may be timed out by CICS Transaction Gateway. ECI timeout can expire before a response is received from CICS. This means that the client does not receive the confirmation from CICS that a unit of work has been backed out or committed.	0	short
encoding	The transfer encoding of the message.	Cp1145	java.lang.String
gatewayFactory	The connection factory to be used		com.redhat.camel.component.cics.pool.CICSGatewayFactory
host	The address of the CICS Transaction Gateway that this instance connects to		java.lang.String
lazyStartProducer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.		boolean
port	The port of the CICS Transaction Gateway that this instance connects to.	2006	int
protocol	the protocol that this component will use to connect to the CICS Transaction Gateway.	tcp	java.lang.String
server	The address of the CICS server that this instance connects to.		java.lang.String

Name	Description	Default	Type
sslKeyring	The full classname of the SSL key ring class or keystore file to be used for the client encrypted connection.		java.lang.String
sslPassword	The password for the encrypted key ring class or keystore		java.lang.String
configuration	To use a shared CICS configuration		com.redhat.camel.component.cics.CICSCSConfiguration
socketConnectionTimeout	The socket connection timeout		int
password	Password to use for authentication		java.lang.String
userId	User ID to use for authentication		java.lang.String

23.5. ENDPOINT OPTIONS

The CICS endpoint is configured using URI syntax:

```
cics://[interfaceType]/[dataExchangeType][?options]
```

With the following *path* and *query* parameters:

23.5.1. Path Parameters (2 parameters)

Name	Description	Default	Type
interfaceType	The interface type, can be eci, esi or epi. at the moment only eci is supported.	eci	java.lang.String
dataExchangeType	The kind of data exchange to use Enum value: - commarea - channel	commarea	com.redhat.camel.component.cics.support.CICSDataExchangeType

23.5.2. Query Parameters (15 parameters)

Name	Description	Default	Type
ctgDebug	Enable debug mode on the underlying IBM CGT client.	false	java.lang.Boolean
eciBinding	The Binding instance to transform a Camel Exchange to EciRequest and vice versa		com.redhat.camel.component.cics.CICSEciBinding
eciTimeout	The ECI timeout value associated with this ECIRequest object. An ECI timeout value of zero indicates that this ECIRequest will not be timed out by CICS Transaction Gateway. An ECI timeout value greater than zero indicates that the ECIRequest may be timed out by CICS Transaction Gateway. ECI timeout can expire before a response is received from CICS. This means that the client does not receive the confirmation from CICS that a unit of work has been backed out or committed.	0	short
encoding	Encoding to convert COMMAREA data to before sending.	Cp1145	java.lang.String
gatewayFactory	The connection factory to use		com.redhat.camel.component.cics.pool.CICSGatewayFactory
host	The address of the CICS Transaction Gateway that this instance connects to	localhost	java.lang.String
port	The port of the CICS Transaction Gateway that this instance connects to.	2006	int
protocol	the protocol that this component will use to connect to the CICS Transaction Gateway.	tcp	java.lang.String
server	The address of the CICS server that this instance connects to		java.lang.String

Name	Description	Default	Type
lazyStartProducer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.		boolean
sslKeyring	The full class name of the SSL key ring class or keystore file to be used for the client encrypted connection		java.lang.String
sslPassword	The password for the encrypted key ring class or keystore		java.lang.String
socketConnectionTimeout	The socket connection timeout		int
password	Password to use for authentication		java.lang.String
userId	User ID to use for authentication		java.lang.String

23.6. MESSAGE HEADERS

The CICS component supports 15 message header(s), which is/are listed below:

Name	Description	Default	Type
CICS_RETURN_CODE Constant: com.redhat.camel.component.cics.CICSConstants#CICS_RETURN_CODE_HEADER	Return code from this flow operation.		int

Name	Description	Default	Type
CICS_RETURN_CODE_STRING Constant: com.redhat.camel.component.cics.CICSCSConstants#CICS_RETURN_CODE_STRING_HEADER	The CICS return code as a String. The String is the name of the appropriate Java constant, for example, if this header is ECI_NO_ERROR, then the String returned will be ECI_NO_ERROR. If this header is unknown then the String returned will be ECI_UNKNOWN_CICS_RC.  NOTE For CICS return codes that may have more than one meaning the String returned is a concatenation of the return codes. The only concatenated String is: ECI_ERR_REQUEST_TIMEOUT_OR_ERR_NO_REPLY.		java.lang.String
CICS_EXTEND_MODE Constant: com.redhat.camel.component.cics.CICSCSConstants#CICS_EXTEND_MODE_HEADER	Extend mode of request. The default value is ECI_NO_EXTEND.		int
CICS_LUW_TOKEN Constant: com.redhat.camel.component.cics.CICSCSConstants#CICS_LUW_TOKEN_HEADER	Extended Logical Unit of Work token. The default value is ECI_LUW_NEW.		int
CICS_PROGRAM_NAME Constant: com.redhat.camel.component.cics.CICSCSConstants#CICS_PROGRAM_NAME_HEADER	Program to invoke on CICS server.		java.lang.String

Name	Description	Default	Type
CICS_TRANSACTION_ID Constant: com.redhat.camel. component.cics.CI CSCConstants#CIC S_TRANSACTION _ID_HEADER	Transaction ID to run CICS program under.		java.lang.String
CICS_COMMAREA_SIZE Constant: com.redhat.camel. component.cics.CI CSCConstants#CIC S_COMM_AREA_S IZE_HEADER	Length of COMMAREA. The default value is 0.		int
CICS_CHANNEL_NAME Constant: com.redhat.camel. component.cics.CI CSCConstants#CIC S_CHANNEL_NA ME_HEADER	The name of the channel to create com.redhat.camel.component.cics.CICSCConstants#C ICS_CHANNEL_NAME_HEADER		java.lang.String
CICS_CONTAINER_NAME Constant: com.redhat.camel. component.cics.CI CSCConstants#CIC S_CONTAINER_N AME_HEADER	The name of the container to create.		java.lang.String
CICS_CHANNEL_CCSID Constant: com.redhat.camel. component.cics.CI CSCConstants#CIC S_CHANNEL_CCS ID_HEADER	The CCSID the channel should set as its default.		int

Name	Description	Default	Type
CICS_SERVER Constant: com.redhat.camel. component.cics.CI CSConstants#CIC S_SERVER_HEAD ER	CICS server to direct request to. This header overrides the value configured in the endpoint.		java.lang.String
CICS_USER_ID Constant: com.redhat.camel. component.cics.CI CSConstants#CIC S_USER_ID_HEAD ER	User ID for CICS server. This header overrides the value configured in the endpoint.		java.lang.String
CICS_PASSWORD Constant: com.redhat.camel. component.cics.CI CSConstants#CIC S_PASSWORD_HE ADER	Password or password phrase for CICS server. This header overrides the value configured in the endpoint.		java.lang.String
CICS_ABEND_CO DE Constant: com.redhat.camel. component.cics.CI CSConstants#CIC S_ABEND_CODE_ HEADER	CICS transaction abend code.		java.lang.String
CICS_ECI_REQUE ST_TIMEOUT Constant: com.redhat.camel. component.cics.CI CSConstants#CIC S_ECI_REQUEST_ TIMEOUT_HEADE R	The value, in seconds, of the ECI timeout for the current ECIRRequest. A value of zero indicates that this ECIRRequest will not be timed out by CICS Transaction Gateway	0	short

Name	Description	Default	Type
CICS_ENCODING Constant: com.redhat.camel. component.cics.CI CSConstants#CIC S_ENCODING_HE ADER	Encoding to convert COMMAREA data to before sending.		String

23.7. SAMPLES

23.7.1. Using Commarea

Following sample show how to configure a route that runs a program on a CICS server using COMMAREA. The COMMAREA size has to be defined in **CICS_COMM_AREA_SIZE** header, while the COMMAREA input data is defined in the Camel Exchange body.

NOTE

You must create a COMMAREA that is large enough to contain all the information to be sent to the server and large enough to contain all the information that can be returned from the server.

```
//....
import static com.redhat.camel.component.cics.CICSConstants.CICS_PROGRAM_NAME_HEADER;
import static
com.redhat.camel.component.cics.CICSConstants.CICS_COMM_AREA_SIZE_HEADER;
//....

from("direct:run").
    setHeader(CICS_PROGRAM_NAME_HEADER, "ECIREADY").
    setHeader(CICS_COMM_AREA_SIZE_HEADER, 18).
    setBody(constant("My input data")).
    to("cics:eci/commarea?host=192.168.0.23&port=2006&protocol=tcp&userId=foo&password=bar");
```

The Outcome of the CICS program invocation is mapped to Camel Exchange in this way:

- The numeric value of return code is stored in the **CICS_RETURN_CODE** header
- The COMMAREA output data is stored in the Camel Exchange Body.

23.7.2. Using Channel with a single input container

Following sample shows how to use a channel with a single container to run a CICS program. The channel name and the container name are taken from headers, and the container value from the body:

```
//....
import static com.redhat.camel.component.cics.CICSConstants.CICS_PROGRAM_NAME_HEADER;
import static com.redhat.camel.component.cics.CICSConstants.CICS_CHANNEL_NAME_HEADER;
```

```
import static
com.redhat.camel.component.cics.CICSConstants.CICS_CONTAINER_NAME_HEADER;

//...
from("direct:run").
    setHeader(CICS_PROGRAM_NAME_HEADER, "EC03").
    setHeader(CICS_CHANNEL_NAME_HEADER, "SAMPLECHANNEL").
    setHeader(CICS_CONTAINER_NAME_HEADER, "INPUTDATA").
    setBody(constant("My input data")).
    to("cics:eci/channel?host=192.168.0.23&port=2006&protocol=tcp&userId=foo&password=bar");
```

The container(s) returned is stored in an **java.util.Map<String, Object>**, the key is the container name and the value is the output data of the container.

23.7.3. Using Channel with multiple input container

If you need to run a CICS program that takes multiple container as input, you can create a **java.util.Map<String, Object>** where the keys are the container names and the values are the input data. In this case the **CICS_CONTAINER_NAME** header is ignored.

```
//....
import static com.redhat.camel.component.cics.CICSConstants.CICS_PROGRAM_NAME_HEADER;
import static com.redhat.camel.component.cics.CICSConstants.CICS_CHANNEL_NAME_HEADER;

//...
from("direct:run").
    setHeader(CICS_PROGRAM_NAME_HEADER, "EC03").
    setHeader(CICS_CHANNEL_NAME_HEADER, "SAMPLECHANNEL").
    process(exchange->{
        byte[] thirdContainerData = HexFormat.of().parseHex("e04fd020ea3a6910a2d808002b30309d");
        Map<String, Object> containers = Map.of(
            "firstContainerName", "firstContainerData",
            "secondContainerName", "secondContainerData",
            "thirdContainerName", thirdContainerData
        );
        exchange.getMessage().setBody(containers);
    }).
    to("cics:eci/channel?host=192.168.0.23&port=2006&protocol=tcp&userId=foo&password=bar");
```

23.8. SPRING BOOT AUTO-CONFIGURATION

The component supports 17 options, which are listed below.

Name	Description	Default	Type
camel.component.cics.binding	The Binding instance to transform a Camel Exchange to EciRequest and vice versa.		com.redhat.camel.component.cics.CICSEciBinding

Name	Description	Default	Type
camel.component.cics.configuration	Configuration.		com.redhat.camel.component.cics.CICSConfiguration
camel.component.cics.ctg-debug	Enable debug mode on the underlying IBM CGT client.		java.lang.Boolean
camel.component.cics.eci-timeout	The ECI timeout value associated with this ECIRequest object. An ECI timeout value of zero indicates that this ECIRequest will not be timed out by CICS Transaction Gateway. An ECI timeout value greater than zero indicates that the ECIRequest may be timed out by CICS Transaction Gateway. ECI timeout can expire before a response is received from CICS. This means that the client does not receive the confirmation from CICS that a unit of work has been backed out or committed.		java.lang.Short
camel.component.cics.enabled	Whether to enable auto configuration of the cics component. This is enabled by default.		java.lang.Boolean
camel.component.cics.encoding	The transfer encoding of the message.	Cp1145	java.lang.String
camel.component.cics.gateway-factory	The connection factory to be use. The option is a com.redhat.camel.component.cics.pool.CICSGatewayFactory type.		com.redhat.camel.component.cics.pool.CICSGatewayFactory
camel.component.cics.host	The address of the CICS Transaction Gateway that this instance connects to		java.lang.String
camel.component.cics.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.		java.lang.Boolean
camel.component.cics.password	Password to use for authentication		java.lang.String

Name	Description	Default	Type
camel.component.cics.port	The port of the CICS Transaction Gateway that this instance connects to.	2006	java.lang.Integer
camel.component.cics.protocol	the protocol that this component will use to connect to the CICS Transaction Gateway.	tcp	java.lang.String
camel.component.cics.server	The address of the CICS server that this instance connects to		java.lang.String
camel.component.cics.socket-connection-timeout	The socket connection timeout		java.lang.Integer
camel.component.cics.ssl-keyring	The full classname of the SSL key ring class or keystore file to be used for the client encrypted connection		java.lang.String
camel.component.cics.ssl-password	The password for the encrypted key ring class or keystore		java.lang.String
camel.component.cics.user-id	User ID to use for authentication		java.lang.String

CHAPTER 24. CONSTANT

The Constant Expression Language is really just a way to use a constant value or object.

NOTE

This is a fixed constant value (or object) that is only set once during starting up the route, do not use this if you want dynamic values during routing.

24.1. DEPENDENCIES

When using **constant** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-core-starter</artifactId>
</dependency>
```

24.2. CONSTANT OPTIONS

The Constant language supports 2 options, which are listed below.

Name	Default	Java Type	Description
resultType		String	Sets the class name of the constant type.
trim		Boolean	Whether to trim the value to remove leading and trailing whitespaces and line breaks.

24.3. EXAMPLE

The **setHeader** EIP can utilize a constant expression like:

```
<route>
  <from uri="seda:a"/>
  <setHeader name="theHeader">
    <constant>the value</constant>
  </setHeader>
  <to uri="mock:b"/>
</route>
```

in this case, the message coming from the seda:a endpoint will have the header with key **theHeader** set its value as **the value** (string type).

And the same example using Java DSL:

```
from("seda:a")
  .setHeader("theHeader", constant("the value"))
  .to("mock:b");
```

24.3.1. Specifying type of value

The option **resultType** can be used to specify the type of the value, when the value is given as a **String** value, which happens when using XML or YAML DSL:

For example to set a header with **int** type you can do:

```
<route>
  <from uri="seda:a"/>
  <setHeader name="zipCode">
    <constant resultType="int">90210</constant>
  </setHeader>
  <to uri="mock:b"/>
</route>
```

24.4. LOADING CONSTANT FROM EXTERNAL RESOURCE

You can externalize the constant and have Camel load it from a resource such as "**classpath:**", "**file:**", or "**http:**".

This is done using the following syntax: "**resource:scheme:location**", eg to refer to a file on the classpath you can do:

```
.setHeader("myHeader").constant("resource:classpath:constant.txt")
```

24.5. DEPENDENCIES

The Constant language is part of **camel-core**.

24.6. SPRING BOOT AUTO-CONFIGURATION

The component supports 147 options, which are listed below.

Name	Description	Default	Type
<code>camel.cloud.consul.service-discovery.acl-token</code>	Sets the ACL token to be used with Consul.		String
<code>camel.cloud.consul.service-discovery.block-seconds</code>	The seconds to wait for a watch event, default 10 seconds.	10	Integer

Name	Description	Default	Type
<code>camel.cloud.consul.service-discovery.configurations</code>	Define additional configuration definitions.		Map
<code>camel.cloud.consul.service-discovery.connect-timeout-millis</code>	Connect timeout for OkHttpClient.		Long
<code>camel.cloud.consul.service-discovery.datacenter</code>	The data center.		String
<code>camel.cloud.consul.service-discovery.enabled</code>	Enable the component.	true	Boolean
<code>camel.cloud.consul.service-discovery.password</code>	Sets the password to be used for basic authentication.		String
<code>camel.cloud.consul.service-discovery.properties</code>	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in <code>com.netflix.client.config.CommonClientConfigKey</code> .		Map
<code>camel.cloud.consul.service-discovery.read-timeout-millis</code>	Read timeout for OkHttpClient.		Long
<code>camel.cloud.consul.service-discovery.url</code>	The Consul agent URL.		String
<code>camel.cloud.consul.service-discovery.username</code>	Sets the username to be used for basic authentication.		String

Name	Description	Default	Type
<code>camel.cloud.console.service-discovery.write-timeout-millis</code>	Write timeout for OkHttpClient.		Long
<code>camel.cloud.dns.service-discovery.configurations</code>	Define additional configuration definitions.		Map
<code>camel.cloud.dns.service-discovery.domain</code>	The domain name;.		String
<code>camel.cloud.dns.service-discovery.enabled</code>	Enable the component.	true	Boolean
<code>camel.cloud.dns.service-discovery.properties</code>	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in <code>com.netflix.client.config.CommonClientConfigKey</code> .		Map
<code>camel.cloud.dns.service-discovery.proto</code>	The transport protocol of the desired service.	<code>_tcp</code>	String
<code>camel.cloud.etcd.service-discovery.configurations</code>	Define additional configuration definitions.		Map
<code>camel.cloud.etcd.service-discovery.enabled</code>	Enable the component.	true	Boolean
<code>camel.cloud.etcd.service-discovery.password</code>	The password to use for basic authentication.		String
<code>camel.cloud.etcd.service-discovery.properties</code>	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in <code>com.netflix.client.config.CommonClientConfigKey</code> .		Map

Name	Description	Default	Type
<code>camel.cloud.etcd.service-discovery.service-path</code>	The path to look for for service discovery.	<code>/services/</code>	String
<code>camel.cloud.etcd.service-discovery.timeout</code>	To set the maximum time an action could take to complete.		Long
<code>camel.cloud.etcd.service-discovery.type</code>	To set the discovery type, valid values are on-demand and watch.	on-demand	String
<code>camel.cloud.etcd.service-discovery.uris</code>	The URIs the client can connect to.		String
<code>camel.cloud.etcd.service-discovery.user-name</code>	The user name to use for basic authentication.		String
<code>camel.cloud.kubernetes.service-discovery.api-version</code>	Sets the API version when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.ca-cert-data</code>	Sets the Certificate Authority data when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.ca-cert-file</code>	Sets the Certificate Authority data that are loaded from the file when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.client-cert-data</code>	Sets the Client Certificate data when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.client-cert-file</code>	Sets the Client Certificate data that are loaded from the file when using client lookup.		String

Name	Description	Default	Type
<code>camel.cloud.kubernetes.service-discovery.client-key-algo</code>	Sets the Client Keystore algorithm, such as RSA when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.client-key-data</code>	Sets the Client Keystore data when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.client-key-file</code>	Sets the Client Keystore data that are loaded from the file when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.client-key-passphrase</code>	Sets the Client Keystore passphrase when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.configurations</code>	Define additional configuration definitions.		Map
<code>camel.cloud.kubernetes.service-discovery.dns-domain</code>	Sets the DNS domain to use for DNS lookup.		String
<code>camel.cloud.kubernetes.service-discovery.enabled</code>	Enable the component.	true	Boolean
<code>camel.cloud.kubernetes.service-discovery.lookup</code>	How to perform service lookup. Possible values: client, dns, environment. When using client, then the client queries the kubernetes master to obtain a list of active pods that provides the service, and then random (or round robin) select a pod. When using dns the service name is resolved as name.namespace.svc.dnsDomain. When using dnssrv the service name is resolved with SRV query forsvc... When using environment then environment variables are used to lookup the service. By default environment is used.	environment	String

Name	Description	Default	Type
<code>camel.cloud.kubernetes.service-discovery.master-url</code>	Sets the URL to the master when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.namespace</code>	Sets the namespace to use. Will by default use namespace from the ENV variable KUBERNETES_MASTER.		String
<code>camel.cloud.kubernetes.service-discovery.oauth-token</code>	Sets the OAUTH token for authentication (instead of username/password) when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.password</code>	Sets the password for authentication when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.port-name</code>	Sets the Port Name to use for DNS/DNSSRV lookup.		String
<code>camel.cloud.kubernetes.service-discovery.port-protocol</code>	Sets the Port Protocol to use for DNS/DNSSRV lookup.		String
<code>camel.cloud.kubernetes.service-discovery.properties</code>	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in <code>com.netflix.client.config.CommonClientConfigKey</code> .		Map
<code>camel.cloud.kubernetes.service-discovery.trust-certs</code>	Sets whether to turn on trust certificate check when using client lookup.	false	Boolean
<code>camel.cloud.kubernetes.service-discovery.username</code>	Sets the username for authentication when using client lookup.		String

Name	Description	Default	Type
<code>camel.cloud.ribbon.load-balancer.client-name</code>	Sets the Ribbon client name.		String
<code>camel.cloud.ribbon.load-balancer.configurations</code>	Define additional configuration definitions.		Map
<code>camel.cloud.ribbon.load-balancer.enabled</code>	Enable the component.	true	Boolean
<code>camel.cloud.ribbon.load-balancer.namespace</code>	The namespace.		String
<code>camel.cloud.ribbon.load-balancer.password</code>	The password.		String
<code>camel.cloud.ribbon.load-balancer.properties</code>	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in <code>com.netflix.client.config.CommonClientConfigKey</code> .		Map
<code>camel.cloud.ribbon.load-balancer.username</code>	The username.		String
<code>camel.hystrix.allow-maximum-size-to-diverge-from-core-size</code>	Allows the configuration for <code>maximumSize</code> to take effect. That value can then be equal to, or higher, than <code>coreSize</code> .	false	Boolean
<code>camel.hystrix.circuit-breaker-enabled</code>	Whether to use a <code>HystrixCircuitBreaker</code> or not. If false no circuit-breaker logic will be used and all requests permitted. This is similar in effect to <code>circuitBreakerForceClosed()</code> except that continues tracking metrics and knowing whether it should be open/closed, this property results in not even instantiating a circuit-breaker.	true	Boolean

Name	Description	Default	Type
camel.hystrix.circuit-breaker-error-threshold-percentage	Error percentage threshold (as whole number such as 50) at which point the circuit breaker will trip open and reject requests. It will stay tripped for the duration defined in <code>circuitBreakerSleepWindowInMilliseconds</code> ; The error percentage this is compared against comes from <code>HystrixCommandMetrics.getHealthCounts()</code> .	50	Integer
camel.hystrix.circuit-breaker-force-closed	If true the <code>HystrixCircuitBreaker#allowRequest()</code> will always return true to allow requests regardless of the error percentage from <code>HystrixCommandMetrics.getHealthCounts()</code> . The <code>circuitBreakerForceOpen()</code> property takes precedence so if it set to true this property does nothing.	false	Boolean
camel.hystrix.circuit-breaker-force-open	If true the <code>HystrixCircuitBreaker.allowRequest()</code> will always return false, causing the circuit to be open (tripped) and reject all requests. This property takes precedence over <code>circuitBreakerForceClosed()</code> ;	false	Boolean
camel.hystrix.circuit-breaker-request-volume-threshold	Minimum number of requests in the <code>metricsRollingStatisticalWindowInMilliseconds()</code> that must exist before the <code>HystrixCircuitBreaker</code> will trip. If below this number the circuit will not trip regardless of error percentage.	20	Integer
camel.hystrix.circuit-breaker-sleep-window-in-milliseconds	The time in milliseconds after a <code>HystrixCircuitBreaker</code> trips open that it should wait before trying requests again.	5000	Integer
camel.hystrix.configurations	Define additional configuration definitions.		Map
camel.hystrix.core-pool-size	Core thread-pool size that gets passed to <code>java.util.concurrent.ThreadPoolExecutor#setCorePoolSize(int)</code> .	10	Integer
camel.hystrix.enabled	Enable the component.	true	Boolean
camel.hystrix.execution-isolation-semaphore-max-concurrent-requests	Number of concurrent requests permitted to <code>HystrixCommand.run()</code> . Requests beyond the concurrent limit will be rejected. Applicable only when <code>executionIsolationStrategy == SEMAPHORE</code> .	20	Integer

Name	Description	Default	Type
camel.hystrix.execution-isolation-strategy	What isolation strategy <code>HystrixCommand.run()</code> will be executed with. If <code>THREAD</code> then it will be executed on a separate thread and concurrent requests limited by the number of threads in the thread-pool. If <code>SEMAPHORE</code> then it will be executed on the calling thread and concurrent requests limited by the semaphore count.	<code>THREAD</code>	String
camel.hystrix.execution-isolation-thread-interrupt-on-timeout	Whether the execution thread should attempt an interrupt (using <code>Future#cancel</code>) when a thread times out. Applicable only when <code>executionIsolationStrategy() == THREAD</code> .	<code>true</code>	Boolean
camel.hystrix.execution-timeout-enabled	Whether the timeout mechanism is enabled for this command.	<code>true</code>	Boolean
camel.hystrix.execution-timeout-in-milliseconds	Time in milliseconds at which point the command will timeout and halt execution. If <code>executionIsolationThreadInterruptOnTimeout == true</code> and the command is thread-isolated, the executing thread will be interrupted. If the command is semaphore-isolated and a <code>HystrixObservableCommand</code> , that command will get unsubscribed.	<code>1000</code>	Integer
camel.hystrix.fallback-enabled	Whether <code>HystrixCommand.getFallback()</code> should be attempted when failure occurs.	<code>true</code>	Boolean
camel.hystrix.fallback-isolation-semaphore-max-concurrent-requests	Number of concurrent requests permitted to <code>HystrixCommand.getFallback()</code> . Requests beyond the concurrent limit will fail-fast and not attempt retrieving a fallback.	<code>10</code>	Integer
camel.hystrix.group-key	Sets the group key to use. The default value is <code>CamelHystrix</code> .	<code>CamelHystrix</code>	String
camel.hystrix.keep-alive-time	Keep-alive time in minutes that gets passed to <code>ThreadPoolExecutor#setKeepAliveTime(long, TimeUnit)</code> .	<code>1</code>	Integer

Name	Description	Default	Type
camel.hystrix.max-queue-size	Max queue size that gets passed to BlockingQueue in HystrixConcurrencyStrategy.getBlockingQueue(int) This should only affect the instantiation of a threadpool - it is not eligible to change a queue size on the fly. For that, use queueSizeRejectionThreshold().	-1	Integer
camel.hystrix.max-imum-size	Maximum thread-pool size that gets passed to ThreadPoolExecutor#setMaximumPoolSize(int) . This is the maximum amount of concurrency that can be supported without starting to reject HystrixCommands. Please note that this setting only takes effect if you also set allowMaximumSizeToDivergeFromCoreSize.	10	Integer
camel.hystrix.metrics-health-snapshot-interval-in-milliseconds	Time in milliseconds to wait between allowing health snapshots to be taken that calculate success and error percentages and affect HystrixCircuitBreaker.isOpen() status. On high-volume circuits the continual calculation of error percentage can become CPU intensive thus this controls how often it is calculated.	500	Integer
camel.hystrix.metrics-rolling-percentile-bucket-size	Maximum number of values stored in each bucket of the rolling percentile. This is passed into HystrixRollingPercentile inside HystrixCommandMetrics.	10	Integer
camel.hystrix.metrics-rolling-percentile-enabled	Whether percentile metrics should be captured using HystrixRollingPercentile inside HystrixCommandMetrics.	true	Boolean
camel.hystrix.metrics-rolling-percentile-window-buckets	Number of buckets the rolling percentile window is broken into. This is passed into HystrixRollingPercentile inside HystrixCommandMetrics.	6	Integer
camel.hystrix.metrics-rolling-percentile-window-in-milliseconds	Duration of percentile rolling window in milliseconds. This is passed into HystrixRollingPercentile inside HystrixCommandMetrics.	10000	Integer
camel.hystrix.metrics-rolling-statistical-window-buckets	Number of buckets the rolling statistical window is broken into. This is passed into HystrixRollingNumber inside HystrixCommandMetrics.	10	Integer

Name	Description	Default	Type
camel.hystrix.metrics-rolling-statistical-window-in-milliseconds	This property sets the duration of the statistical rolling window, in milliseconds. This is how long metrics are kept for the thread pool. The window is divided into buckets and rolls by those increments.	10000	Integer
camel.hystrix.queue-size-rejection-threshold	Queue size rejection threshold is an artificial max size at which rejections will occur even if maxQueueSize has not been reached. This is done because the maxQueueSize of a BlockingQueue can not be dynamically changed and we want to support dynamically changing the queue size that affects rejections. This is used by HystrixCommand when queuing a thread for execution.	5	Integer
camel.hystrix.request-log-enabled	Whether HystrixCommand execution and events should be logged to HystrixRequestLog.	true	Boolean
camel.hystrix.thread-pool-key	Sets the thread pool key to use. Will by default use the same value as groupKey has been configured to use.	Camel Hystrix	String
camel.hystrix.thread-pool-rolling-number-statistical-window-buckets	Number of buckets the rolling statistical window is broken into. This is passed into HystrixRollingNumber inside each HystrixThreadPoolMetrics instance.	10	Integer
camel.hystrix.thread-pool-rolling-number-statistical-window-in-milliseconds	Duration of statistical rolling window in milliseconds. This is passed into HystrixRollingNumber inside each HystrixThreadPoolMetrics instance.	10000	Integer
camel.language.constant.enabled	Whether to enable auto configuration of the constant language. This is enabled by default.		Boolean
camel.language.constant.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
camel.language.csimple.enabled	Whether to enable auto configuration of the csimple language. This is enabled by default.		Boolean

Name	Description	Default	Type
<code>camel.language.csimple.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
<code>camel.language.exchangeproperty.enabled</code>	Whether to enable auto configuration of the exchangeProperty language. This is enabled by default.		Boolean
<code>camel.language.exchangeproperty.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
<code>camel.language.file.enabled</code>	Whether to enable auto configuration of the file language. This is enabled by default.		Boolean
<code>camel.language.file.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
<code>camel.language.header.enabled</code>	Whether to enable auto configuration of the header language. This is enabled by default.		Boolean
<code>camel.language.header.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
<code>camel.language.ref.enabled</code>	Whether to enable auto configuration of the ref language. This is enabled by default.		Boolean
<code>camel.language.ref.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
<code>camel.language.simple.enabled</code>	Whether to enable auto configuration of the simple language. This is enabled by default.		Boolean
<code>camel.language.simple.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
<code>camel.language.tokenize.enabled</code>	Whether to enable auto configuration of the tokenize language. This is enabled by default.		Boolean
<code>camel.language.tokenize.group-delimiter</code>	Sets the delimiter to use when grouping. If this has not been set then token will be used as the delimiter.		String
<code>camel.language.tokenize.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean

Name	Description	Default	Type
camel.resilience4j. .automatic- transition-from- open-to-half- open-enabled	Enables automatic transition from OPEN to HALF_OPEN state once the waitDurationInOpenState has passed.	false	Boolean
camel.resilience4j. .circuit-breaker- ref	Refers to an existing io.github.resilience4j.circuitbreaker.CircuitBreaker instance to lookup and use from the registry. When using this, then any other circuit breaker options are not in use.		String
camel.resilience4j. .config-ref	Refers to an existing io.github.resilience4j.circuitbreaker.CircuitBreakerConfig instance to lookup and use from the registry.		String
camel.resilience4j. .configurations	Define additional configuration definitions.		Map
camel.resilience4j. .enabled	Enable the component.	true	Boolean
camel.resilience4j. .failure-rate- threshold	Configures the failure rate threshold in percentage. If the failure rate is equal or greater than the threshold the CircuitBreaker transitions to open and starts short-circuiting calls. The threshold must be greater than 0 and not greater than 100. Default value is 50 percentage.		Float
camel.resilience4j. .minimum- number-of-calls	Configures the minimum number of calls which are required (per sliding window period) before the CircuitBreaker can calculate the error rate. For example, if minimumNumberOfCalls is 10, then at least 10 calls must be recorded, before the failure rate can be calculated. If only 9 calls have been recorded the CircuitBreaker will not transition to open even if all 9 calls have failed. Default minimumNumberOfCalls is 100.	100	Integer
camel.resilience4j. .permitted- number-of-calls- in-half-open- state	Configures the number of permitted calls when the CircuitBreaker is half open. The size must be greater than 0. Default size is 10.	10	Integer

Name	Description	Default	Type
camel.resilience4j.sliding-window-size	Configures the size of the sliding window which is used to record the outcome of calls when the CircuitBreaker is closed. <code>slidingWindowSize</code> configures the size of the sliding window. Sliding window can either be count-based or time-based. If <code>slidingWindowType</code> is <code>COUNT_BASED</code> , the last <code>slidingWindowSize</code> calls are recorded and aggregated. If <code>slidingWindowType</code> is <code>TIME_BASED</code> , the calls of the last <code>slidingWindowSize</code> seconds are recorded and aggregated. The <code>slidingWindowSize</code> must be greater than 0. The <code>minimumNumberOfCalls</code> must be greater than 0. If the <code>slidingWindowType</code> is <code>COUNT_BASED</code> , the <code>minimumNumberOfCalls</code> cannot be greater than <code>slidingWindowSize</code> . If the <code>slidingWindowType</code> is <code>TIME_BASED</code> , you can pick whatever you want. Default <code>slidingWindowSize</code> is 100.	100	Integer
camel.resilience4j.sliding-window-type	Configures the type of the sliding window which is used to record the outcome of calls when the CircuitBreaker is closed. Sliding window can either be count-based or time-based. If <code>slidingWindowType</code> is <code>COUNT_BASED</code> , the last <code>slidingWindowSize</code> calls are recorded and aggregated. If <code>slidingWindowType</code> is <code>TIME_BASED</code> , the calls of the last <code>slidingWindowSize</code> seconds are recorded and aggregated. Default <code>slidingWindowType</code> is <code>COUNT_BASED</code> .	<code>COUNT_BASED</code>	String
camel.resilience4j.slow-call-duration-threshold	Configures the duration threshold (seconds) above which calls are considered as slow and increase the slow calls percentage. Default value is 60 seconds.	60	Integer
camel.resilience4j.slow-call-rate-threshold	Configures a threshold in percentage. The CircuitBreaker considers a call as slow when the call duration is greater than <code>slowCallDurationThreshold</code> Duration. When the percentage of slow calls is equal or greater the threshold, the CircuitBreaker transitions to open and starts short-circuiting calls. The threshold must be greater than 0 and not greater than 100. Default value is 100 percentage which means that all recorded calls must be slower than <code>slowCallDurationThreshold</code> .		Float
camel.resilience4j.wait-duration-in-open-state	Configures the wait duration (in seconds) which specifies how long the CircuitBreaker should stay open, before it switches to half open. Default value is 60 seconds.	60	Integer

Name	Description	Default	Type
camel.resilience4j.writable-stack-trace-enabled	Enables writable stack traces. When set to false, <code>Exception.getStackTrace</code> returns a zero length array. This may be used to reduce log spam when the circuit breaker is open as the cause of the exceptions is already known (the circuit breaker is short-circuiting calls).	true	Boolean
camel.rest.api-component	The name of the Camel component to use as the REST API (such as swagger) If no API Component has been explicit configured, then Camel will lookup if there is a Camel component responsible for servicing and generating the REST API documentation, or if a <code>org.apache.camel.spi.RestApiProcessorFactory</code> is registered in the registry. If either one is found, then that is being used.		String
camel.rest.api-context-path	Sets a leading API context-path the REST API services will be using. This can be used when using components such as camel-servlet where the deployed web application is deployed using a context-path.		String
camel.rest.api-context-route-id	Sets the route id to use for the route that services the REST API. The route will by default use an auto assigned route id.		String
camel.rest.api-host	To use an specific hostname for the API documentation (eg swagger) This can be used to override the generated host with this configured hostname.		String
camel.rest.api-property	Allows to configure as many additional properties for the api documentation (swagger). For example set property <code>api.title</code> to my cool stuff.		Map
camel.rest.api-vendor-extension	Whether vendor extension is enabled in the Rest APIs. If enabled then Camel will include additional information as vendor extension (eg keys starting with x-) such as route ids, class names etc. Not all 3rd party API gateways and tools supports vendor-extensions when importing your API docs.	false	Boolean
camel.rest.binding-mode	Sets the binding mode to use. The default value is off.		RestBindingMode

Name	Description	Default	Type
camel.rest.client-request-validation	Whether to enable validation of the client request to check whether the Content-Type and Accept headers from the client is supported by the Rest-DSL configuration of its consumes/produces settings. This can be turned on, to enable this check. In case of validation error, then HTTP Status codes 415 or 406 is returned. The default value is false.	false	Boolean
camel.rest.component	The Camel Rest component to use for the REST transport (consumer), such as netty-http, jetty, servlet, undertow. If no component has been explicit configured, then Camel will lookup if there is a Camel component that integrates with the Rest DSL, or if a org.apache.camel.spi.RestConsumerFactory is registered in the registry. If either one is found, then that is being used.		String
camel.rest.component-property	Allows to configure as many additional properties for the rest component in use.		Map
camel.rest.consumer-property	Allows to configure as many additional properties for the rest consumer in use.		Map
camel.rest.context-path	Sets a leading context-path the REST services will be using. This can be used when using components such as camel-servlet where the deployed web application is deployed using a context-path. Or for components such as camel-jetty or camel-netty-http that includes a HTTP server.		String
camel.rest.cors-headers	Allows to configure custom CORS headers.		Map
camel.rest.data-format-property	Allows to configure as many additional properties for the data formats in use. For example set property prettyPrint to true to have json outputted in pretty mode. The properties can be prefixed to denote the option is only for either JSON or XML and for either the IN or the OUT. The prefixes are: json.in. json.out. xml.in. xml.out. For example a key with value xml.out.mustBeJAXBELEMENT is only for the XML data format for the outgoing. A key without a prefix is a common key for all situations.		Map
camel.rest.enable-cors	Whether to enable CORS headers in the HTTP response. The default value is false.	false	Boolean

Name	Description	Default	Type
camel.rest.endpoint-property	Allows to configure as many additional properties for the rest endpoint in use.		Map
camel.rest.host	The hostname to use for exposing the REST service.		String
camel.rest.hostname-resolver	If no hostname has been explicit configured, then this resolver is used to compute the hostname the REST service will be using.		RestHostNameResolver
camel.rest.json-data-format	Name of specific json data format to use. By default json-jackson will be used. Important: This option is only for setting a custom name of the data format, not to refer to an existing data format instance.		String
camel.rest.port	The port number to use for exposing the REST service. Notice if you use servlet component then the port number configured here does not apply, as the port number in use is the actual port number the servlet component is using. eg if using Apache Tomcat its the tomcat http port, if using Apache Karaf its the HTTP service in Karaf that uses port 8181 by default etc. Though in those situations setting the port number here, allows tooling and JMX to know the port number, so its recommended to set the port number to the number that the servlet engine uses.		String
camel.rest.producer-api-doc	Sets the location of the api document (swagger api) the REST producer will use to validate the REST uri and query parameters are valid accordingly to the api document. This requires adding camel-swagger-java to the classpath, and any miss configuration will let Camel fail on startup and report the error(s). The location of the api document is loaded from classpath by default, but you can use file: or http: to refer to resources to load from file or http url.		String
camel.rest.producer-component	Sets the name of the Camel component to use as the REST producer.		String
camel.rest.scheme	The scheme to use for exposing the REST service. Usually http or https is supported. The default value is http.		String
camel.rest.skip-binding-on-error-code	Whether to skip binding on output if there is a custom HTTP error code header. This allows to build custom error messages that do not bind to json / xml etc, as success messages otherwise will do.	false	Boolean

Name	Description	Default	Type
<code>camel.rest.use-x-forward-headers</code>	Whether to use X-Forward headers for Host and related setting. The default value is true.	true	Boolean
<code>camel.rest.xml-data-format</code>	Name of specific XML data format to use. By default JAXB will be used. Important: This option is only for setting a custom name of the data format, not to refer to an existing data format instance.		String
<code>camel.rest.api-context-id-pattern</code>	Deprecated Sets an CamelContext id pattern to only allow Rest APIs from rest services within CamelContext's which name matches the pattern. The pattern name refers to the CamelContext name, to match on the current CamelContext only. For any other value, the pattern uses the rules from <code>PatternHelper#matchPattern(String,String)</code> .		String
<code>camel.rest.api-context-listing</code>	Deprecated Sets whether listing of all available CamelContext's with REST services in the JVM is enabled. If enabled it allows to discover these contexts, if false then only the current CamelContext is in use.	false	Boolean

CHAPTER 25. CONTROL BUS

Only producer is supported

The [Control Bus](#) from the EIP patterns allows for the integration system to be monitored and managed from within the framework.

Use a Control Bus to manage an enterprise integration system. The Control Bus uses the same messaging mechanism used by the application data, but uses separate channels to transmit data that is relevant to the management of components involved in the message flow.

In Camel you can manage and monitor using JMX, or by using a Java API from the **CamelContext**, or from the **org.apache.camel.api.management** package, or use the event notifier which has an example [here](#).

The ControlBus component provides easy management of Camel applications based on the [Control Bus](#) EIP pattern. For example, by sending a message to an Endpoint you can control the lifecycle of routes, or gather performance statistics.

```
controlbus:command[?options]
```

Where **command** can be any string to identify which type of command to use.

25.1. COMMANDS

Command	Description
route	To control routes using the routeId and action parameter.
language	Allows you to specify a to use for evaluating the message body. If there is any result from the evaluation, then the result is put in the message body.

25.2. DEPENDENCIES

When using **controlbus** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-controlbus-starter</artifactId>
</dependency>
```

25.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

25.3.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).
- directly in the Java code.

25.3.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

25.4. COMPONENT OPTIONS

The Control Bus component supports 2 options, which are listed below.

Name	Description	Default	Type
------	-------------	---------	------

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

25.5. ENDPOINT OPTIONS

The Control Bus endpoint is configured using URI syntax:

```
controlbus:command:language
```

with the following path and query parameters:

25.5.1. Path Parameters (2 parameters)

Name	Description	Default	Type
command (producer)	Required Command can be either route or language. Enum values: ● route ● language		String

Name	Description	Default	Type
language (producer)	Allows you to specify the name of a Language to use for evaluating the message body. If there is any result from the evaluation, then the result is put in the message body. Enum values: • bean • constant • el • exchangeProperty • file • groovy • header • jsonpath • mvel • ognl • ref • simple • spel • sql • terser • tokenize • xpath • xquery • xtokenize		Language

25.5.1.1. Query Parameters (6 parameters)

Name	Description	Default	Type
------	-------------	---------	------

Name	Description	Default	Type
action (producer)	To denote an action that can be either: start, stop, or status. To either start or stop a route, or to get the status of the route as output in the message body. You can use suspend and resume from Camel 2.11.1 onwards to either suspend or resume a route. And from Camel 2.11.1 onwards you can use stats to get performance statics returned in XML format; the routeld option can be used to define which route to get the performance stats for, if routeld is not defined, then you get statistics for the entire CamelContext. The restart action will restart the route. Enum values: • start • stop • suspend • resume • restart • status • stats		String
async (producer)	Whether to execute the control bus task asynchronously. Important: If this option is enabled, then any result from the task is not set on the Exchange. This is only possible if executing tasks synchronously.	false	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

Name	Description	Default	Type
loggingLevel (producer)	Logging level used for logging when task is done, or if any exceptions occurred during processing the task. Enum values: • TRACE • DEBUG • INFO • WARN • ERROR • OFF	INFO	LogLevel
restartDelay (producer)	The delay in millis to use when restarting a route.	1000	int
routeId (producer)	To specify a route by its id. The special keyword <code>current</code> indicates the current route.		String

25.6. USING ROUTE COMMAND

The route command allows you to do common tasks on a given route very easily, for example to start a route, you can send an empty message to this endpoint:

```
template.sendBody("controlbus:route?routeId=foo&action=start", null);
```

To get the status of the route, you can do:

```
String status = template.requestBody("controlbus:route?routeId=foo&action=status", null, String.class);
```

25.7. GETTING PERFORMANCE STATISTICS

This requires JMX to be enabled (is by default) then you can get the performance statistics per route, or for the CamelContext. For example to get the statistics for a route named foo, we can do:

```
String xml = template.requestBody("controlbus:route?routeId=foo&action=stats", null, String.class);
```

The returned statistics is in XML format. Its the same data you can get from JMX with the **dumpRouteStatsAsXml** operation on the **ManagedRouteMBean**.

To get statistics for the entire CamelContext you just omit the routeId parameter as shown below:

```
String xml = template.requestBody("controlbus:route?action=stats", null, String.class);
```

25.8. USING SIMPLE LANGUAGE

You can use the [Simple](#) language with the control bus, for example to stop a specific route, you can send a message to the **"controlbus:language:simple"** endpoint containing the following message:

```
template.sendBody("controlbus:language:simple",
    "${camelContext.getRouteController().stopRoute('myRoute')}");
```

As this is a void operation, no result is returned. However, if you want the route status you can do:

```
String status = template.requestBody("controlbus:language:simple",
    "${camelContext.getRouteStatus('myRoute')}", String.class);
```

It's easier to use the **route** command to control lifecycle of routes. The **language** command allows you to execute a language script that has stronger powers such as [Groovy](#) or to some extend the [Simple](#) language.

For example to shutdown Camel itself you can do:

```
template.sendBody("controlbus:language:simple?async=true", "${camelContext.stop()}");
```

We use **async=true** to stop Camel asynchronously as otherwise we would be trying to stop Camel while it was in-flight processing the message we sent to the control bus component.

NOTE

You can also use other languages such as [Groovy](#), etc.

25.9. SPRING BOOT AUTO-CONFIGURATION

The component supports 3 options, which are listed below.

Name	Description	Default	Type
camel.component.controlbus.automated-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.controlbus.enabled	Whether to enable auto configuration of the controlbus component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component-controlbus.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 26. CRON

Only consumer is supported

The Cron component is a generic interface component that allows triggering events at specific time interval specified using the Unix cron syntax (e.g. `0/2 * * * * ?` to trigger an event every two seconds).

Being an interface component, the Cron component does not contain a default implementation, instead it requires that the users plug the implementation of their choice.

The following standard Camel components support the Cron endpoints:

- Camel-quartz
- Camel-spring

The Cron component is also supported in **Camel K**, which can use the Kubernetes scheduler to trigger the routes when required by the cron expression. Camel K does not require additional libraries to be plugged when using cron expressions compatible with Kubernetes cron syntax.

26.1. DEPENDENCIES

When using **cron** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>  
  <groupId>org.apache.camel.springboot</groupId>  
  <artifactId>camel-cron-starter</artifactId>  
</dependency>
```

Additional libraries may be needed in order to plug a specific implementation.

26.2. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

26.2.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).

- directly in the Java code.

26.2.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

26.3. COMPONENT OPTIONS

The Cron component supports 3 options, which are listed below.

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
cronService (advanced)	The id of the CamelCronService to use when multiple implementations are provided.		String

26.4. ENDPOINT OPTIONS

The Cron endpoint is configured using URI syntax:

```
cron:name
```

with the following path and query parameters:

26.4.1. Path Parameters (1 parameters)

Name	Description	Default	Type
name (consumer)	Required The name of the cron trigger.		String

26.4.2. Query Parameters (4 parameters)

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
schedule (consumer)	Required A cron expression that will be used to generate events.		String
exceptionHandler (consumer (advanced))	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut • InOptionalOut		ExchangePattern

26.5. USAGE

The component can be used to trigger events at specified times, as in the following example:

```
from("cron:tab?schedule=0/1+*+*+*+*+*+*+*+*+*")
  .setBody().constant("event")
  .log("${body}");
```

The schedule expression **0/3+10+++*+?** can be also written as **0/3 10 * * * ?** and triggers an event every three seconds only in the tenth minute of each hour.

Parts in the schedule expression means (in order):

- Seconds (optional)
- Minutes
- Hours
- Day of month
- Month
- Day of week
- Year (optional)

Schedule expressions can be made of 5 to 7 parts. When expressions are composed of 6 parts, the first items is the "seconds" part (and year is considered missing).

Other valid examples of schedule expressions are:

- **0/2 * * * ?** (5 parts, an event every two minutes)
- **0 0/2 * * * MON-FRI 2030** (7 parts, an event every two minutes only in year 2030)

Routes can also be written using the XML DSL.

```
<route>
  <from uri="cron:tab?schedule=0/1+*+*+*+*+*+*+*+*+*"/>
  <setBody>
    <constant>event</constant>
  </setBody>
  <to uri="log:info"/>
</route>
```

26.6. SPRING BOOT AUTO-CONFIGURATION

The component supports 4 options, which are listed below.

Name	Description	Default	Type
camel.component.cron.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.cron.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.cron.cron-service	The id of the CamelCronService to use when multiple implementations are provided.		String
camel.component.cron.enabled	Whether to enable auto configuration of the cron component. This is enabled by default.		Boolean

CHAPTER 27. CRYPTO (JCE)

Since Camel 2.3

Only producer is supported

With Camel cryptographic endpoints and Java Cryptographic extension, it is easy to create Digital Signatures for Exchanges. Camel provides a pair of flexible endpoints which get used in concert to create a signature for an exchange in one part of the exchange workflow and then verify the signature in a later part of the workflow.

27.1. DEPENDENCIES

When using **crypto** with Red Hat build of Camel Spring Boot ensure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-crypto-starter</artifactId>
</dependency>
```

27.2. INTRODUCTION

Digital signatures make use of Asymmetric Cryptographic techniques to sign messages. From a high level, the algorithms use pairs of complimentary keys with the special property that data encrypted with one key can only be decrypted with the other. The private key, is closely guarded and used to 'sign' the message while the other, public key, is shared around to anyone interested in verifying the signed messages. Messages are signed by using the private key to encrypting a digest of the message. This encrypted digest is transmitted along with the message. On the other side the verifier recalculates the message digest and uses the public key to decrypt the digest in the signature. If both digests match, the verifier knows only the holder of the private key could have created the signature.

Camel uses the Signature service from the Java Cryptographic Extension to do all the heavy cryptographic lifting required to create exchange signatures. The following are the resources for explaining the mechanics of Cryptography, Message digests and Digital Signatures and how to leverage them with the JCE.

- Bruce Schneier's Applied Cryptography
- Beginning Cryptography with Java by David Hook
- The ever insightful Wikipedia [Digital_signatures](#)

27.3. URI FORMAT

Camel provides a pair of crypto endpoints to create and verify signatures

```
crypto:sign:name[?options]
crypto:verify:name[?options]
```

- **crypto:sign** creates the signature and stores it in the Header keyed by the constant **org.apache.camel.component.crypto.DigitalSignatureConstants.SIGNATURE**, that is, **"CamelDigitalSignature"**.

- **crypto:verify** reads in the contents of this header and do the verification calculation.

To function, the sign and verify process needs a pair of keys to be shared, signing requiring a **PrivateKey** and verifying a **PublicKey** (or a **Certificate** containing one). Using the JCE, it is very simple to generate these key pairs but it is usually most secure to use a KeyStore to house and share your keys. The DSL is very flexible about how keys are supplied and provides a number of mechanisms.

A **crypto:sign** endpoint is typically defined in one route and the complimentary **crypto:verify** in another, though for simplicity in the examples they appear one after the other. Both signing and verifying should be configured identically.

27.4. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

27.4.1. Configuring Component Options

The component level is the highest level which holds general and common configurations that are inherited by the endpoints. For example a component may have security settings, credentials for authentication, urls for network connection and so forth.

Some components only have a few options, and others may have many. Because components typically have pre configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

Configuring components can be done with the [Component DSL](#), in a configuration file (application.properties|yaml), or directly with Java code.

27.4.2. Configuring Endpoint Options

Endpoints have many options, which allows you to configure what you need the endpoint to do. The options are also categorized into whether the endpoint is used as consumer (from) or as a producer (to), or used for both.

Configuring endpoints is done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a *type safe* way of configuring endpoints and data formats in Java.

Use [Property Placeholders](#) to configure options that allows to not hardcode urls, port numbers, sensitive information, and other settings. In other words placeholders allows to externalize the configuration from your code, and gives more flexibility and reuse.

The following two sections lists all the options, firstly for the component followed by the endpoint.

27.5. COMPONENT OPTIONS

The Crypto (JCE) component supports 21 options that are listed below.

Name	Description	Default	Type
algorithm (producer)	Sets the JCE name of the Algorithm that should be used for the signer.	SHA256withRSA	String
alias (producer)	Sets the alias used to query the KeyStore for keys and <code>java.security.cert.Certificate Certificates</code> to be used in signing and verifying exchanges. This value can be provided at runtime via the message header <code>org.apache.camel.component.crypto.DigitalSignatureConstants#KEYSTORE_ALIAS</code> .		String
certificateName (producer)	Sets the reference name for a PrivateKey that can be found in the registry.		String
keystore (producer)	Sets the KeyStore that can contain keys and Certificates for use in signing and verifying exchanges. A KeyStore is typically used with an alias, either one supplied in the Route definition or dynamically via the message header <code>CamelSignatureKeyStoreAlias</code> . If no alias is supplied and there is only a single entry in the Keystore, then this single entry will be used.		KeyStore
keystoreName (producer)	Sets the reference name for a Keystore that can be found in the registry.		String

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
privateKey* (producer)	Set the PrivateKey that should be used to sign the exchange.		PrivateKey
privateKeyName (producer)	Sets the reference name for a PrivateKey that can be found in the registry.		String
provider (producer)	Set the id of the security provider that provides the configured Signature algorithm.		String
publicKeyName (producer)	references that should be resolved when the context changes.		String
secureRandomName (producer)	Sets the reference name for a SecureRandom that can be found in the registry.		String

Name	Description	Default	Type
signatureHeaderName (producer)	Set the name of the message header that should be used to store the base64 encoded signature. This defaults to 'CamelDigitalSignature'.		String
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
bufferSize (advanced)	Set the size of the buffer used to read in the Exchange payload data.	2048	Integer
certificate (advanced)	Set the Certificate that should be used to verify the signature in the exchange based on its payload.		Certificate
clearHeaders (advanced)	Determines if the Signature specific headers be cleared after signing and verification. Defaults to true, and should only be made otherwise at your extreme peril as vital private information such as Keys and passwords may escape if unset.	true	boolean

Name	Description	Default	Type
configuration (advanced)	To use the shared DigitalSignatureConfiguration as configuration.		DigitalSignatureConfiguration
keyStoreParameters (advanced)	Sets the KeyStore that can contain keys and Certificates for use in signing and verifying exchanges based on the given KeyStoreParameters. A KeyStore is typically used with an alias, either one supplied in the Route definition or dynamically via the message header CamelSignatureKeyStoreAlias. If no alias is supplied and there is only a single entry in the Keystore, then this single entry will be used.		KeyStoreParameters
publicKey (advanced)	Set the PublicKey that should be used to verify the signature in the exchange.		PublicKey
secureRandom (advanced)	Set the SecureRandom used to initialize the Signature service.		SecureRandom
password (security)	Sets the password used to access an aliased PrivateKey in the KeyStore.		String

27.6. ENDPOINT OPTIONS

The Crypto (JCE) endpoint is configured using URI syntax:

```
crypto:cryptoOperation:name
```

The following are the path and query parameters:

27.6.1. Path Parameters (2 parameters)

Name	Description	Default	Type
cryptoOperation (producer)	Required Set the Crypto operation from that supplied after the crypto scheme in the endpoint uri e.g. crypto:sign sets sign as the operation. Enum values: * sign * verify		CryptoOperation
name (producer)	Required The logical name of this operation.		String

27.6.2. Query Parameters (19 parameters)

Name	Description	Default	Type
algorithm (producer)	Sets the JCE name of the Algorithm that should be used for the signer.	SHA256withRSA	String
alias (producer)	Sets the alias used to query the KeyStore for keys and <code>java.security.cert.Certificate Certificates</code> to be used in signing and verifying exchanges. This value can be provided at runtime via the message header <code>org.apache.camel.component.crypto.DigitalSignatureConstants#KEYSTORE_ALIAS</code>.		String
certificateName (producer)	Sets the reference name for a PrivateKey that can be found in the registry.		String

Name	Description	Default	Type
keystore (producer)	Sets the KeyStore that can contain keys and Certificates for use in signing and verifying exchanges. A KeyStore is typically used with an alias, either one supplied in the Route definition or dynamically via the message header <code>CamelSignatureKeyStoreAlias</code> . If no alias is supplied and there is only a single entry in the Keystore, then this single entry will be used.		KeyStore
keystoreName (producer)	Sets the reference name for a Keystore that can be found in the registry.		String
privateKey (producer)	Set the PrivateKey that should be used to sign the exchange.		PrivateKey
privateKeyName (producer)	Sets the reference name for a PrivateKey that can be found in the registry.		String
provider (producer)	Set the id of the security provider that provides the configured Signature algorithm.		String
publicKeyName (producer)	references that should be resolved when the context changes.		String
secureRandomName (producer)	Sets the reference name for a SecureRandom that can be found in the registry.		String

Name	Description	Default	Type
signatureHeaderName (producer)	Set the name of the message header that should be used to store the base64 encoded signature. This defaults to 'CamelDigitalSignature'.		String
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages using Camel routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time.	false	boolean
bufferSize (advanced)	Set the size of the buffer used to read in the Exchange payload data.	2048	Integer
certificate (advanced)	Set the Certificate that should be used to verify the signature in the exchange based on its payload.		Certificate

Name	Description	Default	Type
clearHeaders (advanced)	Determines if the Signature specific headers be cleared after signing and verification. Defaults to true, and should only be made otherwise at your extreme peril as vital private information such as Keys and passwords may escape if unset.	true	boolean
keyStoreParameters (advanced)	Sets the KeyStore that can contain keys and Certificates for use in signing and verifying exchanges based on the given KeyStoreParameters. A KeyStore is typically used with an alias, either one supplied in the Route definition or dynamically via the message header CamelSignatureKeyStoreAlias. If no alias is supplied and there is only a single entry in the Keystore, then this single entry will be used.		KeyStoreParameters
publicKey (advanced)	Set the PublicKey that should be used to verify the signature in the exchange.		PublicKey
secureRandom (advanced)	Set the SecureRandom used to initialize the Signature service.		SecureRandom
password (security)	Sets the password used to access an aliased PrivateKey in the KeyStore.		String

27.7. MESSAGE HEADERS

The Crypto (JCE) component supports 4 message headers that are listed below.

Name	Description	Default	Type
[CamelSignaturePrivateKey (producer) Constant: SIGNATURE_PRIVATE_KEY	The PrivateKey that should be used to sign the message.		PrivateKey
[CamelSignaturePublicKeyOrCert (producer) Constant: SIGNATURE_PUBLIC_KEY_OR_CERT	The Certificate or PublicKey that should be used to verify the signature.		Certificate or PublicKey
CamelSignatureKeyStoreAlias (producer) Constant: KEYSTORE_ALIAS	The alias used to query the KeyStore for keys and Certificates to be used in signing and verifying exchanges.		String
CamelSignatureKeyStorePassword (producer) Constant: KEYSTORE_PASSWORD	The password used to access an aliased PrivateKey in the KeyStore.		char[]

27.8. USING

27.8.1. Raw keys

The most basic way to sign and verify an exchange is with a KeyPair as follows.

```

KeyPair keyPair = KeyGenerator.getInstance("RSA").generateKeyPair();

from("direct:sign")
  .setHeader(DigitalSignatureConstants.SIGNATURE_PRIVATE_KEY, constant(keys.getPrivate()))
  .to("crypto:sign:message")
  .to("direct:verify");

from("direct:verify")
  .setHeader(DigitalSignatureConstants.SIGNATURE_PUBLIC_KEY_OR_CERT,
    constant(keys.getPublic()))
  .to("crypto:verify:check");

```

The same can be achieved with the [Spring XML Extensions](#) using references to keys.

27.8.2. KeyStores and Aliases.

The JCE provides a very versatile keystore concept for housing pairs of private keys and certificates, keeping them encrypted and password protected. They can be retrieved by applying an alias to the retrieval APIs. There are a number of ways to get keys and Certificates into a keystore, most often this is done with the external 'keytool' application.

The following command will create a keystore containing a key and certificate aliased by **bob**, which can be used in the following examples. The password for the keystore and the key is **letmein**.

```
keytool -genkey -keyalg RSA -keysize 2048 -keystore keystore.jks -storepass letmein -alias bob -
dname "CN=Bob,OU=IT,O=Camel" -noprompt
```

The following route first signs an exchange using Bob's alias from the KeyStore bound into the Camel Registry, and then verifies it using the same alias.

```
from("direct:sign")
  .to("crypto:sign:keystoreSign?alias=bob&keystoreName=myKeystore&password=letmein")
  .log("Signature: ${header.CamelDigitalSignature}")
  .to("crypto:verify:keystoreVerify?alias=bob&keystoreName=myKeystore&password=letmein")
  .log("Verified: ${body}");
```

The following code shows how to load the keystore created using the above **keytool** command and bind it into the registry with the name **myKeystore** for use in the above route. The example makes use of the **@Configuration** and **@BindToRegistry** annotations introduced in Camel 3 to instantiate the KeyStore and register it with the name **myKeyStore**.

```
@Configuration
public class KeystoreConfig {

    @BindToRegistry
    public KeyStore myKeystore() throws Exception {
        KeyStore store = KeyStore.getInstance("JKS");
        try (FileInputStream fis = new FileInputStream("keystore.jks")) {
            store.load(fis, "letmein".toCharArray());
        }
        return store;
    }
}
```

Again in Spring a ref is used to lookup an actual keystore instance.

27.8.3. Changing JCE Provider and Algorithm

Changing the Signature algorithm or the Security provider is a simple matter of specifying their names. You will need to also use Keys that are compatible with the algorithm you choose.

27.8.4. Changing the Signature Message Header

It may be desirable to change the message header used to store the signature. A different header name can be specified in the route definition as follows

```
from("direct:sign")
  .to("crypto:sign:keystoreSign?
alias=bob&keystoreName=myKeystore&password=letmein&signatureHeaderName=mySignature")
  .log("Signature: ${header.mySignature}")
```

```
.to("crypto:verify:keystoreVerify?
alias=bob&keystoreName=myKeystore&password=letmein&signatureHeaderName=mySignature");
```

===Changing the bufferSize

In case you need to update the size of the buffer.

27.8.5. Supplying Keys dynamically.

When using a Recipient list or similar EIP, the recipient of an exchange can vary dynamically. Using the same key across all recipients may be neither feasible nor desirable. It would be useful to be able to specify signature keys dynamically on a per-exchange basis. The exchange could then be dynamically enriched with the key of its target recipient prior to signing. To facilitate this the signature mechanisms allow for keys to be supplied dynamically via the message headers below.

- **DigitalSignatureConstants.SIGNATURE_PRIVATE_KEY, "CamelSignaturePrivateKey"**
- **DigitalSignatureConstants.SIGNATURE_PUBLIC_KEY_OR_CERT, "CamelSignaturePublicKeyOrCert"**

Even better would be to dynamically supply a keystore alias. Again the alias can be supplied in a message header

- **DigitalSignatureConstants.KEYSTORE_ALIAS, "CamelSignatureKeyStoreAlias"**

The header would be set as follows:

```
Exchange unsigned = getMandatoryEndpoint("direct:alias-sign").createExchange();
unsigned.getIn().setBody(payload);
unsigned.getIn().setHeader(DigitalSignatureConstants.KEYSTORE_ALIAS, "bob");
unsigned.getIn().setHeader(DigitalSignatureConstants.KEYSTORE_PASSWORD,
"letmein".toCharArray());
template.send("direct:alias-sign", unsigned);
Exchange signed = getMandatoryEndpoint("direct:alias-sign").createExchange();
signed.getIn().copyFrom(unsigned.getMessage());
signed.getIn().setHeader(DigitalSignatureConstants.KEYSTORE_ALIAS, "bob");
template.send("direct:alias-verify", signed);
```

27.9. SPRING BOOT AUTO-CONFIGURATION

The component supports 47 options that are listed below.

Name	Description	Default	Type
camel.component.crypt.to.algorithm	Sets the JCE name of the Algorithm that should be used for the signer.	SHA256withRSA	String

Name	Description	Default	Type
camel.component.crypto.alias	Sets the alias used to query the KeyStore for keys and <code>{link java.security.cert.Certificate Certificates}</code> to be used in signing and verifying exchanges. This value can be provided at runtime via the message header <code>org.apache.camel.component.crypto.DigitalSignatureConstants#KEYSTORE_ALIAS</code> .		String
camel.component.crypto.autowired-enabled	Whether auto-wiring is enabled. This is used for automatic auto-wiring options (the option must be marked as auto-wired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.crypto.buffer-size	Set the size of the buffer used to read in the Exchange payload data.	2048	Integer
camel.component.crypto.certificate	Set the Certificate that should be used to verify the signature in the exchange based on its payload. The option is a <code>java.security.cert.Certificate</code> type.		Certificate
camel.component.crypto.certificate-name	Sets the reference name for a <code>PrivateKey</code> that can be found in the registry.		String

Name	Description	Default	Type
camel.component.crypto.clear-headers	Determines if the Signature specific headers be cleared after signing and verification. Defaults to true, and should only be made otherwise at your extreme peril as vital private information such as Keys and passwords may escape if unset.	true	Boolean
camel.component.crypto.configuration	To use the shared DigitalSignatureConfiguration as configuration. The option is a org.apache.camel.component.crypto.DigitalSignatureConfiguration type.		DigitalSignatureConfiguration
camel.component.crypto.enabled	Whether to enable auto configuration of the crypto component. This is enabled by default.		Boolean
camel.component.crypto.key-store-parameters	Sets the KeyStore that can contain keys and Certificates for use in signing and verifying exchanges based on the given KeyStoreParameters. A KeyStore is typically used with an alias, either one supplied in the Route definition or dynamically via the message header CamelSignatureKeyStoreAlias. If no alias is supplied and there is only a single entry in the Keystore, then this single entry will be used. The option is a org.apache.camel.support.jsse.KeyStoreParameters type.		KeyStoreParameters

Name	Description	Default	Type
camel.component.crypto.keystore	Sets the KeyStore that can contain keys and Certificates for use in signing and verifying exchanges. A KeyStore is typically used with an alias, either one supplied in the Route definition or dynamically via the message header <code>CamelSignatureKeyStoreAlias</code> . If no alias is supplied and there is only a single entry in the Keystore, then this single entry will be used. The option is a <code>java.security.KeyStore</code> type.		KeyStore
camel.component.crypto.keystore-name	Sets the reference name for a Keystore that can be found in the registry.		String
camel.component.crypto.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow <code>CamelContext</code> and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.crypto.password	Sets the password used to access an aliased PrivateKey in the KeyStore.		String
camel.component.crypto.private-key	Set the PrivateKey that should be used to sign the exchange. The option is a java.security.PrivateKey type.		PrivateKey
camel.component.crypto.private-key-name	Sets the reference name for a PrivateKey that can be found in the registry.		String
camel.component.crypto.provider	Set the id of the security provider that provides the configured Signature algorithm.		String
camel.component.crypto.public-key	Set the PublicKey that should be used to verify the signature in the exchange. The option is a java.security.PublicKey type.		PublicKey
camel.component.crypto.public-key-name	references that should be resolved when the context changes.		String
camel.component.crypto.secure-random	Set the SecureRandom used to initialize the Signature service. The option is a java.security.SecureRandom type.		SecureRandom
camel.component.crypto.secure-random-name	Sets the reference name for a SecureRandom that can be found in the registry.		String

Name	Description	Default	Type
camel.component.crypto.signature-header-name	Set the name of the message header that should be used to store the base64 encoded signature. This defaults to 'CamelDigitalSignature'.		String
camel.dataformat.crypto.algorithm	The JCE algorithm name indicating the cryptographic algorithm that will be used.		String
camel.dataformat.crypto.algorithm-parameter-ref	A JCE AlgorithmParameterSpec used to initialize the Cipher. Will lookup the type using the given name as a java.security.spec.AlgorithmParameterSpec type.		String
camel.dataformat.crypto.buffer-size	The size of the buffer used in the signature process.	4096	Integer
camel.dataformat.crypto.crypto-provider	The name of the JCE Security Provider that should be used.		String
camel.dataformat.crypto.enabled	Whether to enable auto configuration of the crypto data format. This is enabled by default.		Boolean
camel.dataformat.crypto.init-vector-ref	Refers to a byte array containing the Initialization Vector that will be used to initialize the Cipher.		String
camel.dataformat.crypto.inline	Flag indicating that the configured IV should be inlined into the encrypted data stream. Is by default false.	false	Boolean
camel.dataformat.crypto.key-ref	Refers to the secret key to lookup from the register to use.		String

Name	Description	Default	Type
camel.dataformat.cryptomac-algorithm	The JCE algorithm name indicating the Message Authentication algorithm.	HmacSHA1	String
camel.dataformat.cryptom.should-append-h-m-a-c	Flag indicating that a Message Authentication Code should be calculated and appended to the encrypted data.	true	Boolean
camel.dataformat.pgpp.algorithm	Symmetric key encryption algorithm; possible values are defined in org.bouncycastle.bcpkg.SymmetricKeyAlgorithmTags; for example 2 (= TRIPLE DES), 3 (= CAST5), 4 (= BLOWFISH), 6 (= DES), 7 (= AES_128). Only relevant for encrypting.		Integer
camel.dataformat.pgpp. armored	This option will cause PGP to base64 encode the encrypted text, making it available for copy/paste, etc.	false	Boolean
camel.dataformat.pgpp.compression-algorithm	Compression algorithm; possible values are defined in org.bouncycastle.bcpkg.CompressionAlgorithmTags; for example 0 (= UNCOMPRESSED), 1 (= ZIP), 2 (= ZLIB), 3 (= BZIP2). Only relevant for encrypting.		Integer
camel.dataformat.pgpp.enabled	Whether to enable auto configuration of the pgp data format. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.dataformat.pgp.hash-algorithm	Signature hash algorithm; possible values are defined in org.bouncycastle.bcpg.HashAlgorithmTags; for example 2 (= SHA1), 8 (= SHA256), 9 (= SHA384), 10 (= SHA512), 11 (=SHA224). Only relevant for signing.		Integer
camel.dataformat.pgp.integrity	Adds an integrity check/sign into the encryption file. The default value is true.	true	Boolean
camel.dataformat.pgp.key-file-name	Filename of the keyring; must be accessible as a classpath resource (but you can specify a location in the file system by using the file: prefix).		String
camel.dataformat.pgp.key-userid	The user ID of the key in the PGP keyring used during encryption. Can also be only a part of a user ID. For example, if the user ID is Test User then you can use the part Test User or to address the user ID.		String
camel.dataformat.pgp.password	Password used when opening the private key (not used for encryption).		String

Name	Description	Default	Type
camel.dataformat.pgp.provider	Java Cryptography Extension (JCE) provider, default is Bouncy Castle (BC). Alternatively you can use, for example, the IAIK JCE provider; in this case the provider must be registered beforehand and the Bouncy Castle provider must not be registered beforehand. The Sun JCE provider does not work.		String
camel.dataformat.pgp.signature-key-file-name	Filename of the keyring to use for signing (during encryption) or for signature verification (during decryption); must be accessible as a classpath resource (but you can specify a location in the file system by using the file: prefix).		String
camel.dataformat.pgp.signature-key-ring	Keyring used for signing/verifying as byte array. You can not set the signatureKeyFileName and signatureKeyRing at the same time.		String

Name	Description	Default	Type
camel.dataformat.pgp. signature-key-userid	User ID of the key in the PGP keyring used for signing (during encryption) or signature verification (during decryption). During the signature verification process the specified User ID restricts the public keys from the public keyring which can be used for the verification. If no User ID is specified for the signature verification then any public key in the public keyring can be used for the verification. Can also be only a part of a user ID. For example, if the user ID is Test User then you can use the part Test User or to address the User ID.		String
camel.dataformat.pgp. signature-password	Password used when opening the private key used for signing (during encryption).		String

Name	Description	Default	Type
camel.dataformat.pgp.signature-verification-option	Controls the behavior for verifying the signature during un-marshaling. There are 4 values possible: optional: The PGP message may or may not contain signatures; if it does contain signatures, then a signature verification is executed. required: The PGP message must contain at least one signature; if this is not the case an exception (PGPException) is thrown. A signature verification is executed. ignore: Contained signatures in the PGP message are ignored; no signature verification is executed. no_signature_allowed: The PGP message must not contain a signature; otherwise an exception (PGPException) is thrown.		String

CHAPTER 28. CSIMPLE

The CSimple language is **compiled** Simple language.

28.1. DEPENDENCIES

When using **csimple** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-core-starter</artifactId>
</dependency>
```

28.2. DIFFERENT BETWEEN CSIMPLE AND SIMPLE

The simple language is a dynamic expression language which is runtime parsed into a set of Camel Expressions or Predicates.

The csimple language is parsed into regular Java source code and compiled together with all the other source code, or compiled once during bootstrap via the **camel-csimple-joor** module.

The simple language is generally very lightweight and fast, however for some use-cases with dynamic method calls via OGNL paths, then the simple language does runtime introspection and reflection calls. This has an overhead on performance, and was one of the reasons why csimple was created.

The csimple language requires to be typesafe and method calls via OGNL paths requires to know the type during parsing. This means for csimple languages expressions you would need to provide the class type in the script, whereas simple introspects this at runtime.

In other words the simple language is using *duck typing* (if it looks like a duck, and quacks like a duck, then it is a duck) and csimple is using Java type (typesafety). If there is a type error then simple will report this at runtime, and with csimple there will be a Java compilation error.

28.2.1. Additional CSimple functions

The csimple language includes some additional functions to support common use-cases working with **Collection**, **Map** or array types. The following functions *bodyAsIndex*, *headerAsIndex*, and *exchangePropertyAsIndex* is used for these use-cases as they are typed.

Function	Type	Description
<code>bodyAsIndex(type, index)</code>	Type	To be used for collecting the body from an existing Collection , Map or array (lookup by the index) and then converting the body to the given type determined by its classname. The converted body can be null.
<code>mandatoryBodyAsIndex(type, index)</code>	Type	To be used for collecting the body from an existing Collection , Map or array (lookup by the index) and then converting the body to the given type determined by its classname. Expects the body to be not null.

Function	Type	Description
<code>headerAsIndex(key, type, index)</code>	Type	To be used for collecting a header from an existing Collection , Map or array (lookup by the index) and then converting the header value to the given type determined by its classname. The converted header can be null.
<code>mandatoryHeaderAsIndex(key, type, index)</code>	Type	To be used for collecting a header from an existing Collection , Map or array (lookup by the index) and then converting the header value to the given type determined by its classname. Expects the header to be not null.
<code>exchangePropertyAsIndex(key, type, index)</code>	Type	To be used for collecting an exchange property from an existing Collection , Map or array (lookup by the index) and then converting the exchange property to the given type determined by its classname. The converted exchange property can be null.
<code>mandatoryExchangePropertyAsIndex(key, type, index)</code>	Type	To be used for collecting an exchange property from an existing Collection , Map or array (lookup by the index) and then converting the exchange property to the given type determined by its classname. Expects the exchange property to be not null.

For example given the following simple expression:

```
Hello ${body[0].name}
```

This script has no type information, and the simple language will resolve this at runtime, by introspecting the message body and if it's a collection based then lookup the first element, and then invoke a method named **getName** via reflection.

In csimple (compiled) we want to pre compile this and therefore the end user must provide type information with the *bodyAsIndex* function:

```
Hello ${bodyAsIndex(com.foo.MyUser, 0).name}
```

28.3. COMPILATION

The csimple language is parsed into regular Java source code and compiled together with all the other source code, or it can be compiled once during bootstrap via the **camel-csimple-joor** module.

There are two ways to compile csimple

- using the **camel-csimple-maven-plugin** generating source code at built time.
- using **camel-csimple-joor** which does runtime in-memory compilation during bootstrap of Camel.

28.3.1. Using camel-csimple-maven-plugin

The **camel-csimple-maven-plugin** Maven plugin is used for discovering all the csimple scripts from the source code, and then automatic generate source code in the **src/generated/java** folder, which then gets compiled together with all the other sources.

The maven plugin will do source code scanning of **.java** and **.xml** files (Java and XML DSL). The scanner limits to detect certain code patterns, and it may miss discovering some csimple scripts if they are being used in unusual/rare ways.

The runtime compilation using **camel-csimple-joor** does not have this limitation.

The benefit is all the csimple scripts will be compiled using the regular Java compiler and therefore everything is included out of the box as **.class** files in the application JAR file, and no additional dependencies is required at runtime.

To use **camel-csimple-maven-plugin** you need to add it to your **pom.xml** file as shown:

```
<plugins>
  <!-- generate source code for csimple languages -->
  <plugin>
    <groupId>org.apache.camel</groupId>
    <artifactId>camel-csimple-maven-plugin</artifactId>
    <version>${camel.version}</version>
    <executions>
      <execution>
        <id>generate</id>
        <goals>
          <goal>generate</goal>
        </goals>
      </execution>
    </executions>
  </plugin>
  <!-- include source code generated to maven sources paths -->
  <plugin>
    <groupId>org.codehaus.mojo</groupId>
    <artifactId>build-helper-maven-plugin</artifactId>
    <version>3.1.0</version>
    <executions>
      <execution>
        <phase>generate-sources</phase>
        <goals>
          <goal>add-source</goal>
          <goal>add-resource</goal>
        </goals>
        <configuration>
          <sources>
            <source>src/generated/java</source>
          </sources>
          <resources>
            <resource>
              <directory>src/generated/resources</directory>
            </resource>
          </resources>
        </configuration>
      </execution>
    </executions>
  </plugin>
</plugins>
```

```

    </executions>
  </plugin>
</plugins>

```

And then you must also add the **build-helper-maven-plugin** Maven plugin to include **src/generated** to the list of source folders for the Java compiler, to ensure the generated source code is compiled and included in the application JAR file.

See the **camel-example-csimple** example at [Camel Examples](#) which uses the maven plugin.

28.3.2. Using camel-csimple-joor

The jOOR library integrates with the Java compiler and performs runtime compilation of Java code.

The supported runtime when using **camel-simple-joor** is intended for Java standalone, Spring Boot, Camel Quarkus and other microservices runtimes. It is not supported in OSGi, Camel Karaf or any kind of Java Application Server runtime.

jOOR does not support runtime compilation with Spring Boot using *fat jar* packaging (<https://github.com/jOOQ/jOOR/issues/69>), it works with exploded classpath.

To use **camel-simple-joor** you simply just add it as dependency to the classpath:

```

<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-csimple-joor</artifactId>
  <version>{CamelSBProjectVersion}</version>
</dependency>

```

There is no need for adding Maven plugins to the **pom.xml** file.

See the **camel-example-csimple-joor** example at [Camel Examples](#) which uses the jOOR compiler.

28.4. CSIMPLE LANGUAGE OPTIONS

The CSimple language supports 2 options, which are listed below.

Name	Default	Java Type	Description
resultType		String	Sets the class name of the result type (type from output).
trim		Boolean	Whether to trim the value to remove leading and trailing whitespaces and line breaks.

28.5. LIMITATIONS

Currently, the csimple language does **not** support:

- nested functions (aka functions inside functions)

- the *null safe* operator (`?`).

For example the following scripts cannot compile:

```
Hello ${bean:greeter(${body}, ${header.counter})}
```

```
${bodyAs(MyUser)?.address?.zip} > 10000
```

28.6. AUTO IMPORTS

The csimple language will automatically import from:

```
import java.util.*;
import java.util.concurrent.*;
import java.util.stream.*;
import org.apache.camel.*;
import org.apache.camel.util.*;
```

28.7. CONFIGURATION FILE

You can configure the csimple language in the **camel-csimple.properties** file which is loaded from the root classpath.

For example you can add additional imports in the **camel-csimple.properties** file by adding:

```
import com.foo.MyUser;
import com.bar.*;
import static com.foo.MyHelper.*;
```

You can also add aliases (key=value) where an alias will be used as a shorthand replacement in the code.

```
echo()=${bodyAs(String)} ${bodyAs(String)}
```

Which allows to use `echo()` in the csimple language script such as:

```
from("direct:hello")
  .transform(csimple("Hello echo()"))
  .log("You said ${body}");
```

The `echo()` alias will be replaced with its value resulting in a script as:

```
.transform(csimple("Hello ${bodyAs(String)} ${bodyAs(String)}"))
```

28.8. SEE ALSO

See the [Simple](#) language as **csimple** has the same set of functions as simple language.

28.9. SPRING BOOT AUTO-CONFIGURATION

The component supports 147 options, which are listed below.

Name	Description	Default	Type
<code>camel.cloud.consul.service-discovery.acl-token</code>	Sets the ACL token to be used with Consul.		String
<code>camel.cloud.consul.service-discovery.block-seconds</code>	The seconds to wait for a watch event, default 10 seconds.	10	Integer
<code>camel.cloud.consul.service-discovery.configurations</code>	Define additional configuration definitions.		Map
<code>camel.cloud.consul.service-discovery.connect-timeout-millis</code>	Connect timeout for OkHttpClient.		Long
<code>camel.cloud.consul.service-discovery.datacenter</code>	The data center.		String
<code>camel.cloud.consul.service-discovery.enabled</code>	Enable the component.	true	Boolean
<code>camel.cloud.consul.service-discovery.password</code>	Sets the password to be used for basic authentication.		String
<code>camel.cloud.consul.service-discovery.properties</code>	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in <code>com.netflix.client.config.CommonClientConfigKey</code> .		Map
<code>camel.cloud.consul.service-discovery.read-timeout-millis</code>	Read timeout for OkHttpClient.		Long
<code>camel.cloud.consul.service-discovery.url</code>	The Consul agent URL.		String

Name	Description	Default	Type
<code>camel.cloud.consul.service-discovery.username</code>	Sets the username to be used for basic authentication.		String
<code>camel.cloud.consul.service-discovery.write-timeout-millis</code>	Write timeout for OkHttpClient.		Long
<code>camel.cloud.dns.service-discovery.configurations</code>	Define additional configuration definitions.		Map
<code>camel.cloud.dns.service-discovery.domain</code>	The domain name;.		String
<code>camel.cloud.dns.service-discovery.enabled</code>	Enable the component.	true	Boolean
<code>camel.cloud.dns.service-discovery.properties</code>	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in <code>com.netflix.client.config.CommonClientConfigKey</code> .		Map
<code>camel.cloud.dns.service-discovery.proto</code>	The transport protocol of the desired service.	<code>_tcp</code>	String
<code>camel.cloud.etcd.service-discovery.configurations</code>	Define additional configuration definitions.		Map
<code>camel.cloud.etcd.service-discovery.enabled</code>	Enable the component.	true	Boolean
<code>camel.cloud.etcd.service-discovery.password</code>	The password to use for basic authentication.		String

Name	Description	Default	Type
<code>camel.cloud.etcd.service-discovery.properties</code>	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in <code>com.netflix.client.config.CommonClientConfigKey</code> .		Map
<code>camel.cloud.etcd.service-discovery.service-path</code>	The path to look for for service discovery.	<code>/services/</code>	String
<code>camel.cloud.etcd.service-discovery.timeout</code>	To set the maximum time an action could take to complete.		Long
<code>camel.cloud.etcd.service-discovery.type</code>	To set the discovery type, valid values are on-demand and watch.	on-demand	String
<code>camel.cloud.etcd.service-discovery.uris</code>	The URIs the client can connect to.		String
<code>camel.cloud.etcd.service-discovery.user-name</code>	The user name to use for basic authentication.		String
<code>camel.cloud.kubernetes.service-discovery.api-version</code>	Sets the API version when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.ca-cert-data</code>	Sets the Certificate Authority data when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.ca-cert-file</code>	Sets the Certificate Authority data that are loaded from the file when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.client-cert-data</code>	Sets the Client Certificate data when using client lookup.		String

Name	Description	Default	Type
<code>camel.cloud.kubernetes.service-discovery.client-cert-file</code>	Sets the Client Certificate data that are loaded from the file when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.client-key-algo</code>	Sets the Client Keystore algorithm, such as RSA when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.client-key-data</code>	Sets the Client Keystore data when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.client-key-file</code>	Sets the Client Keystore data that are loaded from the file when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.client-key-passphrase</code>	Sets the Client Keystore passphrase when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.configurations</code>	Define additional configuration definitions.		Map
<code>camel.cloud.kubernetes.service-discovery.dns-domain</code>	Sets the DNS domain to use for DNS lookup.		String
<code>camel.cloud.kubernetes.service-discovery.enabled</code>	Enable the component.	true	Boolean

Name	Description	Default	Type
camel.cloud.kubernetes.service-discovery.lookup	How to perform service lookup. Possible values: client, dns, environment. When using client, then the client queries the kubernetes master to obtain a list of active pods that provides the service, and then random (or round robin) select a pod. When using dns the service name is resolved as name.namespace.svc.dnsDomain. When using dnssrv the service name is resolved with SRV query forsvc... When using environment then environment variables are used to lookup the service. By default environment is used.	environment	String
camel.cloud.kubernetes.service-discovery.master-url	Sets the URL to the master when using client lookup.		String
camel.cloud.kubernetes.service-discovery.namespace	Sets the namespace to use. Will by default use namespace from the ENV variable KUBERNETES_MASTER.		String
camel.cloud.kubernetes.service-discovery.oauth-token	Sets the OAUTH token for authentication (instead of username/password) when using client lookup.		String
camel.cloud.kubernetes.service-discovery.password	Sets the password for authentication when using client lookup.		String
camel.cloud.kubernetes.service-discovery.port-name	Sets the Port Name to use for DNS/DNSSRV lookup.		String
camel.cloud.kubernetes.service-discovery.port-protocol	Sets the Port Protocol to use for DNS/DNSSRV lookup.		String
camel.cloud.kubernetes.service-discovery.properties	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in com.netflix.client.config.CommonClientConfigKey.		Map

Name	Description	Default	Type
<code>camel.cloud.kubernetes.service-discovery.trust-certs</code>	Sets whether to turn on trust certificate check when using client lookup.	false	Boolean
<code>camel.cloud.kubernetes.service-discovery.username</code>	Sets the username for authentication when using client lookup.		String
<code>camel.cloud.ribbon.load-balancer.client-name</code>	Sets the Ribbon client name.		String
<code>camel.cloud.ribbon.load-balancer.configurations</code>	Define additional configuration definitions.		Map
<code>camel.cloud.ribbon.load-balancer.enabled</code>	Enable the component.	true	Boolean
<code>camel.cloud.ribbon.load-balancer.namespace</code>	The namespace.		String
<code>camel.cloud.ribbon.load-balancer.password</code>	The password.		String
<code>camel.cloud.ribbon.load-balancer.properties</code>	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in <code>com.netflix.client.config.CommonClientConfigKey</code> .		Map
<code>camel.cloud.ribbon.load-balancer.username</code>	The username.		String

Name	Description	Default	Type
camel.hystrix.allow-maximum-size-to-diverge-from-core-size	Allows the configuration for <code>maximumSize</code> to take effect. That value can then be equal to, or higher, than <code>coreSize</code> .	false	Boolean
camel.hystrix.circuit-breaker-enabled	Whether to use a <code>HystrixCircuitBreaker</code> or not. If false no circuit-breaker logic will be used and all requests permitted. This is similar in effect to <code>circuitBreakerForceClosed()</code> except that continues tracking metrics and knowing whether it should be open/closed, this property results in not even instantiating a circuit-breaker.	true	Boolean
camel.hystrix.circuit-breaker-error-threshold-percentage	Error percentage threshold (as whole number such as 50) at which point the circuit breaker will trip open and reject requests. It will stay tripped for the duration defined in <code>circuitBreakerSleepWindowInMilliseconds</code> ; The error percentage this is compared against comes from <code>HystrixCommandMetrics.getHealthCounts()</code> .	50	Integer
camel.hystrix.circuit-breaker-force-closed	If true the <code>HystrixCircuitBreaker#allowRequest()</code> will always return true to allow requests regardless of the error percentage from <code>HystrixCommandMetrics.getHealthCounts()</code> . The <code>circuitBreakerForceOpen()</code> property takes precedence so if it set to true this property does nothing.	false	Boolean
camel.hystrix.circuit-breaker-force-open	If true the <code>HystrixCircuitBreaker.allowRequest()</code> will always return false, causing the circuit to be open (tripped) and reject all requests. This property takes precedence over <code>circuitBreakerForceClosed()</code> .	false	Boolean
camel.hystrix.circuit-breaker-request-volume-threshold	Minimum number of requests in the <code>metricsRollingStatisticalWindowInMilliseconds()</code> that must exist before the <code>HystrixCircuitBreaker</code> will trip. If below this number the circuit will not trip regardless of error percentage.	20	Integer
camel.hystrix.circuit-breaker-sleep-window-in-milliseconds	The time in milliseconds after a <code>HystrixCircuitBreaker</code> trips open that it should wait before trying requests again.	5000	Integer
camel.hystrix.configurations	Define additional configuration definitions.		Map

Name	Description	Default	Type
camel.hystrix.core-pool-size	Core thread-pool size that gets passed to <code>java.util.concurrent.ThreadPoolExecutor#setCorePoolSize(int)</code> .	10	Integer
camel.hystrix.enabled	Enable the component.	true	Boolean
camel.hystrix.execution-isolation-semaphore-max-concurrent-requests	Number of concurrent requests permitted to <code>HystrixCommand.run()</code> . Requests beyond the concurrent limit will be rejected. Applicable only when <code>executionIsolationStrategy == SEMAPHORE</code> .	20	Integer
camel.hystrix.execution-isolation-strategy	What isolation strategy <code>HystrixCommand.run()</code> will be executed with. If <code>THREAD</code> then it will be executed on a separate thread and concurrent requests limited by the number of threads in the thread-pool. If <code>SEMAPHORE</code> then it will be executed on the calling thread and concurrent requests limited by the semaphore count.	THREAD	String
camel.hystrix.execution-isolation-thread-interrupt-on-timeout	Whether the execution thread should attempt an interrupt (using <code>Future#cancel()</code>) when a thread times out. Applicable only when <code>executionIsolationStrategy() == THREAD</code> .	true	Boolean
camel.hystrix.execution-timeout-enabled	Whether the timeout mechanism is enabled for this command.	true	Boolean
camel.hystrix.execution-timeout-in-milliseconds	Time in milliseconds at which point the command will timeout and halt execution. If <code>executionIsolationThreadInterruptOnTimeout == true</code> and the command is thread-isolated, the executing thread will be interrupted. If the command is semaphore-isolated and a <code>HystrixObservableCommand</code> , that command will get unsubscribed.	1000	Integer
camel.hystrix.fallback-ack-enabled	Whether <code>HystrixCommand.getFallback()</code> should be attempted when failure occurs.	true	Boolean
camel.hystrix.fallback-isolation-semaphore-max-concurrent-requests	Number of concurrent requests permitted to <code>HystrixCommand.getFallback()</code> . Requests beyond the concurrent limit will fail-fast and not attempt retrieving a fallback.	10	Integer

Name	Description	Default	Type
camel.hystrix.group-key	Sets the group key to use. The default value is CamelHystrix.	Camel Hystrix	String
camel.hystrix.keep-alive-time	Keep-alive time in minutes that gets passed to <code>ThreadPoolExecutor#setKeepAliveTime(long, TimeUnit)</code> .	1	Integer
camel.hystrix.max-queue-size	Max queue size that gets passed to <code>BlockingQueue</code> in <code>HystrixConcurrencyStrategy.getBlockingQueue(int)</code> . This should only affect the instantiation of a threadpool - it is not eligible to change a queue size on the fly. For that, use <code>queueSizeRejectionThreshold()</code> .	-1	Integer
camel.hystrix.maximum-size	Maximum thread-pool size that gets passed to <code>ThreadPoolExecutor#setMaximumPoolSize(int)</code> . This is the maximum amount of concurrency that can be supported without starting to reject <code>HystrixCommands</code> . Please note that this setting only takes effect if you also set <code>allowMaximumSizeToDivergeFromCoreSize</code> .	10	Integer
camel.hystrix.metrics-health-snapshot-interval-in-milliseconds	Time in milliseconds to wait between allowing health snapshots to be taken that calculate success and error percentages and affect <code>HystrixCircuitBreaker.isOpen()</code> status. On high-volume circuits the continual calculation of error percentage can become CPU intensive thus this controls how often it is calculated.	500	Integer
camel.hystrix.metrics-rolling-percentile-bucket-size	Maximum number of values stored in each bucket of the rolling percentile. This is passed into <code>HystrixRollingPercentile</code> inside <code>HystrixCommandMetrics</code> .	10	Integer
camel.hystrix.metrics-rolling-percentile-enabled	Whether percentile metrics should be captured using <code>HystrixRollingPercentile</code> inside <code>HystrixCommandMetrics</code> .	true	Boolean
camel.hystrix.metrics-rolling-percentile-window-buckets	Number of buckets the rolling percentile window is broken into. This is passed into <code>HystrixRollingPercentile</code> inside <code>HystrixCommandMetrics</code> .	6	Integer

Name	Description	Default	Type
camel.hystrix.metrics-rolling-percentile-window-in-milliseconds	Duration of percentile rolling window in milliseconds. This is passed into HystrixRollingPercentile inside HystrixCommandMetrics.	10000	Integer
camel.hystrix.metrics-rolling-statistical-window-buckets	Number of buckets the rolling statistical window is broken into. This is passed into HystrixRollingNumber inside HystrixCommandMetrics.	10	Integer
camel.hystrix.metrics-rolling-statistical-window-in-milliseconds	This property sets the duration of the statistical rolling window, in milliseconds. This is how long metrics are kept for the thread pool. The window is divided into buckets and rolls by those increments.	10000	Integer
camel.hystrix.queue-size-rejection-threshold	Queue size rejection threshold is an artificial max size at which rejections will occur even if maxQueueSize has not been reached. This is done because the maxQueueSize of a BlockingQueue can not be dynamically changed and we want to support dynamically changing the queue size that affects rejections. This is used by HystrixCommand when queuing a thread for execution.	5	Integer
camel.hystrix.request-log-enabled	Whether HystrixCommand execution and events should be logged to HystrixRequestLog.	true	Boolean
camel.hystrix.thread-pool-key	Sets the thread pool key to use. Will by default use the same value as groupKey has been configured to use.	Camel Hystrix	String
camel.hystrix.thread-pool-rolling-number-statistical-window-buckets	Number of buckets the rolling statistical window is broken into. This is passed into HystrixRollingNumber inside each HystrixThreadPoolMetrics instance.	10	Integer
camel.hystrix.thread-pool-rolling-number-statistical-window-in-milliseconds	Duration of statistical rolling window in milliseconds. This is passed into HystrixRollingNumber inside each HystrixThreadPoolMetrics instance.	10000	Integer
camel.language.constant.enabled	Whether to enable auto configuration of the constant language. This is enabled by default.		Boolean

Name	Description	Default	Type
<code>camel.language.constant.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
<code>camel.language.csimple.enabled</code>	Whether to enable auto configuration of the csimple language. This is enabled by default.		Boolean
<code>camel.language.csimple.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
<code>camel.language.exchangeproperty.enabled</code>	Whether to enable auto configuration of the exchangeProperty language. This is enabled by default.		Boolean
<code>camel.language.exchangeproperty.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
<code>camel.language.file.enabled</code>	Whether to enable auto configuration of the file language. This is enabled by default.		Boolean
<code>camel.language.file.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
<code>camel.language.header.enabled</code>	Whether to enable auto configuration of the header language. This is enabled by default.		Boolean
<code>camel.language.header.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
<code>camel.language.ref.enabled</code>	Whether to enable auto configuration of the ref language. This is enabled by default.		Boolean
<code>camel.language.ref.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
<code>camel.language.simple.enabled</code>	Whether to enable auto configuration of the simple language. This is enabled by default.		Boolean
<code>camel.language.simple.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean

Name	Description	Default	Type
<code>camel.language.tokenize.enabled</code>	Whether to enable auto configuration of the tokenize language. This is enabled by default.		Boolean
<code>camel.language.tokenize.group-delimiter</code>	Sets the delimiter to use when grouping. If this has not been set then token will be used as the delimiter.		String
<code>camel.language.tokenize.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
<code>camel.resilience4j.automatic-transition-from-open-to-half-open-enabled</code>	Enables automatic transition from OPEN to HALF_OPEN state once the <code>waitDurationInOpenState</code> has passed.	false	Boolean
<code>camel.resilience4j.circuit-breaker-ref</code>	Refers to an existing <code>io.github.resilience4j.circuitbreaker.CircuitBreaker</code> instance to lookup and use from the registry. When using this, then any other circuit breaker options are not in use.		String
<code>camel.resilience4j.config-ref</code>	Refers to an existing <code>io.github.resilience4j.circuitbreaker.CircuitBreakerConfig</code> instance to lookup and use from the registry.		String
<code>camel.resilience4j.configurations</code>	Define additional configuration definitions.		Map
<code>camel.resilience4j.enabled</code>	Enable the component.	true	Boolean
<code>camel.resilience4j.failure-rate-threshold</code>	Configures the failure rate threshold in percentage. If the failure rate is equal or greater than the threshold the <code>CircuitBreaker</code> transitions to open and starts short-circuiting calls. The threshold must be greater than 0 and not greater than 100. Default value is 50 percentage.		Float

Name	Description	Default	Type
camel.resilience4j.minimum-number-of-calls	Configures the minimum number of calls which are required (per sliding window period) before the CircuitBreaker can calculate the error rate. For example, if <code>minimumNumberOfCalls</code> is 10, then at least 10 calls must be recorded, before the failure rate can be calculated. If only 9 calls have been recorded the CircuitBreaker will not transition to open even if all 9 calls have failed. Default <code>minimumNumberOfCalls</code> is 100.	100	Integer
camel.resilience4j.permitted-number-of-calls-in-half-open-state	Configures the number of permitted calls when the CircuitBreaker is half open. The size must be greater than 0. Default size is 10.	10	Integer
camel.resilience4j.sliding-window-size	Configures the size of the sliding window which is used to record the outcome of calls when the CircuitBreaker is closed. <code>slidingWindowSize</code> configures the size of the sliding window. Sliding window can either be count-based or time-based. If <code>slidingWindowType</code> is <code>COUNT_BASED</code> , the last <code>slidingWindowSize</code> calls are recorded and aggregated. If <code>slidingWindowType</code> is <code>TIME_BASED</code> , the calls of the last <code>slidingWindowSize</code> seconds are recorded and aggregated. The <code>slidingWindowSize</code> must be greater than 0. The <code>minimumNumberOfCalls</code> must be greater than 0. If the <code>slidingWindowType</code> is <code>COUNT_BASED</code> , the <code>minimumNumberOfCalls</code> cannot be greater than <code>slidingWindowSize</code> . If the <code>slidingWindowType</code> is <code>TIME_BASED</code> , you can pick whatever you want. Default <code>slidingWindowSize</code> is 100.	100	Integer
camel.resilience4j.sliding-window-type	Configures the type of the sliding window which is used to record the outcome of calls when the CircuitBreaker is closed. Sliding window can either be count-based or time-based. If <code>slidingWindowType</code> is <code>COUNT_BASED</code> , the last <code>slidingWindowSize</code> calls are recorded and aggregated. If <code>slidingWindowType</code> is <code>TIME_BASED</code> , the calls of the last <code>slidingWindowSize</code> seconds are recorded and aggregated. Default <code>slidingWindowType</code> is <code>COUNT_BASED</code> .	<code>COUNT_BASED</code>	String
camel.resilience4j.slow-call-duration-threshold	Configures the duration threshold (seconds) above which calls are considered as slow and increase the slow calls percentage. Default value is 60 seconds.	60	Integer

Name	Description	Default	Type
camel.resilience4j.slow-call-rate-threshold	Configures a threshold in percentage. The CircuitBreaker considers a call as slow when the call duration is greater than <code>slowCallDurationThreshold</code> . When the percentage of slow calls is equal or greater the threshold, the CircuitBreaker transitions to open and starts short-circuiting calls. The threshold must be greater than 0 and not greater than 100. Default value is 100 percentage which means that all recorded calls must be slower than <code>slowCallDurationThreshold</code> .		Float
camel.resilience4j.wait-duration-in-open-state	Configures the wait duration (in seconds) which specifies how long the CircuitBreaker should stay open, before it switches to half open. Default value is 60 seconds.	60	Integer
camel.resilience4j.writable-stack-trace-enabled	Enables writable stack traces. When set to false, <code>Exception.getStackTrace</code> returns a zero length array. This may be used to reduce log spam when the circuit breaker is open as the cause of the exceptions is already known (the circuit breaker is short-circuiting calls).	true	Boolean
camel.rest.api-component	The name of the Camel component to use as the REST API (such as swagger) If no API Component has been explicit configured, then Camel will lookup if there is a Camel component responsible for servicing and generating the REST API documentation, or if a <code>org.apache.camel.spi.RestApiProcessorFactory</code> is registered in the registry. If either one is found, then that is being used.		String
camel.rest.api-context-path	Sets a leading API context-path the REST API services will be using. This can be used when using components such as <code>camel-servlet</code> where the deployed web application is deployed using a context-path.		String
camel.rest.api-context-route-id	Sets the route id to use for the route that services the REST API. The route will by default use an auto assigned route id.		String
camel.rest.api-host	To use an specific hostname for the API documentation (eg swagger) This can be used to override the generated host with this configured hostname.		String

Name	Description	Default	Type
camel.rest.api-property	Allows to configure as many additional properties for the api documentation (swagger). For example set property api.title to my cool stuff.		Map
camel.rest.api-vendor-extension	Whether vendor extension is enabled in the Rest APIs. If enabled then Camel will include additional information as vendor extension (eg keys starting with x-) such as route ids, class names etc. Not all 3rd party API gateways and tools supports vendor-extensions when importing your API docs.	false	Boolean
camel.rest.binding-mode	Sets the binding mode to use. The default value is off.		RestBindingMode
camel.rest.client-request-validation	Whether to enable validation of the client request to check whether the Content-Type and Accept headers from the client is supported by the Rest-DSL configuration of its consumes/produces settings. This can be turned on, to enable this check. In case of validation error, then HTTP Status codes 415 or 406 is returned. The default value is false.	false	Boolean
camel.rest.component	The Camel Rest component to use for the REST transport (consumer), such as netty-http, jetty, servlet, undertow. If no component has been explicit configured, then Camel will lookup if there is a Camel component that integrates with the Rest DSL, or if a org.apache.camel.spi.RestConsumerFactory is registered in the registry. If either one is found, then that is being used.		String
camel.rest.component-property	Allows to configure as many additional properties for the rest component in use.		Map
camel.rest.consumer-property	Allows to configure as many additional properties for the rest consumer in use.		Map
camel.rest.context-path	Sets a leading context-path the REST services will be using. This can be used when using components such as camel-servlet where the deployed web application is deployed using a context-path. Or for components such as camel-jetty or camel-netty-http that includes a HTTP server.		String
camel.rest.cors-headers	Allows to configure custom CORS headers.		Map

Name	Description	Default	Type
camel.rest.data-format-property	Allows to configure as many additional properties for the data formats in use. For example set property <code>prettyPrint</code> to <code>true</code> to have json outputted in pretty mode. The properties can be prefixed to denote the option is only for either JSON or XML and for either the IN or the OUT. The prefixes are: <code>json.in</code> , <code>json.out</code> , <code>xml.in</code> , <code>xml.out</code> . For example a key with value <code>xml.out.mustBeJAXBElement</code> is only for the XML data format for the outgoing. A key without a prefix is a common key for all situations.		Map
camel.rest.enable-cors	Whether to enable CORS headers in the HTTP response. The default value is false.	false	Boolean
camel.rest.endpoint-property	Allows to configure as many additional properties for the rest endpoint in use.		Map
camel.rest.host	The hostname to use for exposing the REST service.		String
camel.rest.host-name-resolver	If no hostname has been explicit configured, then this resolver is used to compute the hostname the REST service will be using.		RestHostNameResolver
camel.rest.json-data-format	Name of specific json data format to use. By default <code>json-jackson</code> will be used. Important: This option is only for setting a custom name of the data format, not to refer to an existing data format instance.		String
camel.rest.port	The port number to use for exposing the REST service. Notice if you use servlet component then the port number configured here does not apply, as the port number in use is the actual port number the servlet component is using. eg if using Apache Tomcat its the tomcat http port, if using Apache Karaf its the HTTP service in Karaf that uses port 8181 by default etc. Though in those situations setting the port number here, allows tooling and JMX to know the port number, so its recommended to set the port number to the number that the servlet engine uses.		String
camel.rest.producer-api-doc	Sets the location of the api document (swagger api) the REST producer will use to validate the REST uri and query parameters are valid accordingly to the api document. This requires adding <code>camel-swagger-java</code> to the classpath, and any miss configuration will let Camel fail on startup and report the error(s). The location of the api document is loaded from classpath by default, but you can use <code>file:</code> or <code>http:</code> to refer to resources to load from file or http url.		String

Name	Description	Default	Type
camel.rest.producer-component	Sets the name of the Camel component to use as the REST producer.		String
camel.rest.scheme	The scheme to use for exposing the REST service. Usually http or https is supported. The default value is http.		String
camel.rest.skip-binding-on-error-code	Whether to skip binding on output if there is a custom HTTP error code header. This allows to build custom error messages that do not bind to json / xml etc, as success messages otherwise will do.	false	Boolean
camel.rest.use-x-forward-headers	Whether to use X-Forward headers for Host and related setting. The default value is true.	true	Boolean
camel.rest.xml-data-format	Name of specific XML data format to use. By default jaxb will be used. Important: This option is only for setting a custom name of the data format, not to refer to an existing data format instance.		String
camel.rest.api-context-id-pattern	Deprecated Sets an CamelContext id pattern to only allow Rest APIs from rest services within CamelContext's which name matches the pattern. The pattern name refers to the CamelContext name, to match on the current CamelContext only. For any other value, the pattern uses the rules from PatternHelper#matchPattern(String,String).		String
camel.rest.api-context-listing	Deprecated Sets whether listing of all available CamelContext's with REST services in the JVM is enabled. If enabled it allows to discover these contexts, if false then only the current CamelContext is in use.	false	Boolean

CHAPTER 29. CXF

Both producer and consumer are supported

The CXF component provides integration with [Apache CXF](#) for connecting to [JAX-WS](#) services hosted in CXF.

TIP

When using CXF in streaming modes (see `DataFormat` option), then also read about Stream caching.

29.1. DEPENDENCIES

When using **cxf** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-cxf-soap-starter</artifactId>
</dependency>
```

29.2. URI FORMAT

There are two URI formats for this endpoint: **cxfEndpoint** and **someAddress**.

```
cxf:bean:cxfEndpoint[?options]
```

Where **cxfEndpoint** represents a bean ID that references a bean in the Spring bean registry. With this URI format, most of the endpoint details are specified in the bean definition.

```
cxf://someAddress[?options]
```

Where **someAddress** specifies the CXF endpoint's address. With this URI format, most of the endpoint details are specified using options.

For either style above, you can append options to the URI as follows:

```
cxf:bean:cxfEndpoint?wsdlURL=wsdl/hello_world.wsdl&dataFormat=PAYLOAD
```

29.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

29.3.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings,

credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).
- directly in the Java code.

29.3.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

29.4. COMPONENT OPTIONS

The CXF component supports 6 options, which are listed below.

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
allowStreaming (advanced)	This option controls whether the CXF component, when running in PAYLOAD mode, will DOM parse the incoming messages into DOM Elements or keep the payload as a javax.xml.transform.Source object that would allow streaming in some cases.		Boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
headerFilterStrategy (filter)	To use a custom org.apache.camel.spi.HeaderFilterStrategy to filter header to and from Camel message.		HeaderFilterStrategy
useGlobalSslContextParameters (security)	Enable usage of global SSL context parameters.	false	boolean

29.5. ENDPOINT OPTIONS

The CXF endpoint is configured using URI syntax:

```
cxf:beanId:address
```

with the following path and query parameters:

29.5.1. Path Parameters (2 parameters)

Name	Description	Default	Type
beanId (common)	To lookup an existing configured CxfEndpoint. Must used bean: as prefix.		String
address (service)	The service publish address.		String

29.5.2. Query Parameters (35 parameters)

Name	Description	Default	Type
dataFormat (common)	The data type messages supported by the CXF endpoint. Enum values: • PAYLOAD • RAW • MESSAGE • CXF_MESSAGE • POJO	POJO	DataFormat
wrappedStyle (common)	The WSDL style that describes how parameters are represented in the SOAP body. If the value is false, CXF will chose the document-literal unwrapped style, If the value is true, CXF will chose the document-literal wrapped style.		Boolean
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler

Name	Description	Default	Type
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: ● InOnly ● InOut ● InOptionalOut		ExchangePattern
cookieHandler (producer)	Configure a cookie handler to maintain a HTTP session.		CookieHandler
defaultOperationName (producer)	This option will set the default operationName that will be used by the CxfProducer which invokes the remote service.		String
defaultOperationNamespace (producer)	This option will set the default operationNamespace that will be used by the CxfProducer which invokes the remote service.		String
hostnameVerifier (producer)	The hostname verifier to be used. Use the # notation to reference a HostnameVerifier from the registry.		HostnameVerifier
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
sslContextParameters (producer)	The Camel SSL setting reference. Use the # notation to reference the SSL Context.		SSLContextParameters
wrapped (producer)	Which kind of operation that CXF endpoint producer will invoke.	false	boolean
synchronous (producer (advanced))	Sets whether synchronous processing should be strictly used.	false	boolean

Name	Description	Default	Type
allowStreaming (advanced)	This option controls whether the CXF component, when running in PAYLOAD mode, will DOM parse the incoming messages into DOM Elements or keep the payload as a javax.xml.transform.Source object that would allow streaming in some cases.		Boolean
bus (advanced)	To use a custom configured CXF Bus.		Bus
continuationTimeout (advanced)	This option is used to set the CXF continuation timeout which could be used in CxfConsumer by default when the CXF server is using Jetty or Servlet transport.	30000	long
cxfBinding (advanced)	To use a custom CxfBinding to control the binding between Camel Message and CXF Message.		CxfBinding
cxfConfigurer (advanced)	This option could apply the implementation of org.apache.camel.component.cxf.CxfEndpointConfigurer which supports to configure the CXF endpoint in programmatic way. User can configure the CXF server and client by implementing configure{ServerClient} method of CxfEndpointConfigurer.		CxfConfigurer
defaultBus (advanced)	Will set the default bus when CXF endpoint create a bus by itself.	false	boolean
headerFilterStrategy (advanced)	To use a custom HeaderFilterStrategy to filter header to and from Camel message.		HeaderFilterStrategy
mergeProtocolHeaders (advanced)	Whether to merge protocol headers. If enabled then propagating headers between Camel and CXF becomes more consistent and similar. For more details see CAMEL-6393.	false	boolean
mtomEnabled (advanced)	To enable MTOM (attachments). This requires to use POJO or PAYLOAD data format mode.	false	boolean
properties (advanced)	To set additional CXF options using the key/value pairs from the Map. For example to turn on stacktraces in SOAP faults, properties.faultStackTraceEnabled=true.		Map
skipPayloadMessagePartCheck (advanced)	Sets whether SOAP message validation should be disabled.	false	boolean

Name	Description	Default	Type
loggingFeatureEnabled (logging)	This option enables CXF Logging Feature which writes inbound and outbound SOAP messages to log.	false	boolean
loggingSizeLimit (logging)	To limit the total size of number of bytes the logger will output when logging feature has been enabled and -1 for no limit.	49152	int
skipFaultLogging (logging)	This option controls whether the PhaseInterceptorChain skips logging the Fault that it catches.	false	boolean
password (security)	This option is used to set the basic authentication information of password for the CXF client.		String
username (security)	This option is used to set the basic authentication information of username for the CXF client.		String
bindingId (service)	The bindingId for the service model to use.		String
portName (service)	The endpoint name this service is implementing, it maps to the wsdl:portname. In the format of ns:PORT_NAME where ns is a namespace prefix valid at this scope.		String
publishedEndpointUrl (service)	This option can override the endpointUrl that published from the WSDL which can be accessed with service address url plus wsdl.		String
serviceClass (service)	The class name of the SEI (Service Endpoint Interface) class which could have JSR181 annotation or not.		Class
serviceName (service)	The service name this service is implementing, it maps to the wsdl:servicename.		String
wsdlURL (service)	The location of the WSDL. Can be on the classpath, file system, or be hosted remotely.		String

The **serviceName** and **portName** are [QNames](#), so if you provide them be sure to prefix them with their {namespace} as shown in the examples above.

29.5.3. Descriptions of the dataformats

In Apache Camel, the Camel CXF component is the key to integrating routes with Web services. You can use the Camel CXF component to create a CXF endpoint, which can be used in either of the following ways:

- **Consumer** – (at the start of a route) represents a Web service instance, which integrates with the route. The type of payload injected into the route depends on the value of the endpoint's `dataFormat` option.
- **Producer** – (at other points in the route) represents a WS client proxy, which converts the current exchange object into an operation invocation on a remote Web service. The format of the current exchange must match the endpoint's `dataFormat` setting.

DataFormat	Description
POJO	POJOs (Plain old Java objects) are the Java parameters to the method being invoked on the target server. Both Protocol and Logical JAX-WS handlers are supported.
PAYLOAD	PAYLOAD is the message payload (the contents of the soap:body) after message configuration in the CXF endpoint is applied. Only Protocol JAX-WS handler is supported. Logical JAX-WS handler is not supported.
RAW	RAW mode provides the raw message stream that is received from the transport layer. It is not possible to touch or change the stream, some of the CXF interceptors will be removed if you are using this kind of DataFormat, so you can't see any soap headers after the camel-cxf consumer. JAX-WS handler is not supported.
CXF_MESSAGE	CXF_MESSAGE allows for invoking the full capabilities of CXF interceptors by converting the message from the transport layer into a raw SOAP message

You can determine the data format mode of an exchange by retrieving the exchange property, **CamelCXFDataFormat**. The exchange key constant is defined in **org.apache.camel.component.cxf.common.message.CxfConstants.DATA_FORMAT_PROPERTY**.

29.5.4. How to enable CXF's LoggingOutInterceptor in RAW mode

CXF's **LoggingOutInterceptor** outputs outbound message that goes on the wire to logging system (Java Util Logging). Since the **LoggingOutInterceptor** is in **PRE_STREAM** phase (but **PRE_STREAM** phase is removed in **RAW** mode), you have to configure **LoggingOutInterceptor** to be run during the **WRITE** phase. The following is an example.

```
@Bean
public CxfEndpoint serviceEndpoint(LoggingOutInterceptor loggingOutInterceptor) {
    CxfSpringEndpoint cxfEndpoint = new CxfSpringEndpoint();
    cxfEndpoint.setAddress("http://localhost:" + port
        + "/services" + SERVICE_ADDRESS);
    cxfEndpoint.setServiceClass(org.apache.camel.component.cxf.HelloService.class);
    Map<String, Object> properties = new HashMap<String, Object>();
    properties.put("dataFormat", "RAW");
    cxfEndpoint.setProperties(properties);
    cxfEndpoint.getOutInterceptors().add(loggingOutInterceptor);
}
```

```

    return cxfEndpoint;
}

@Bean
public LoggingOutInterceptor loggingOutInterceptor() {
    LoggingOutInterceptor logger = new LoggingOutInterceptor("write");
    return logger;
}

```

29.5.5. Description of relayHeaders option

There are *in-band* and *out-of-band* on-the-wire headers from the perspective of a JAXWS WSDL-first developer.

The *in-band* headers are headers that are explicitly defined as part of the WSDL binding contract for an endpoint such as SOAP headers.

The *out-of-band* headers are headers that are serialized over the wire, but are not explicitly part of the WSDL binding contract.

Headers relaying/filtering is bi-directional.

When a route has a CXF endpoint and the developer needs to have on-the-wire headers, such as SOAP headers, be relayed along the route to be consumed say by another JAXWS endpoint, then **relayHeaders** should be set to **true**, which is the default value.

29.5.6. Available only in POJO mode

The **relayHeaders=true** expresses an intent to relay the headers. The actual decision on whether a given header is relayed is delegated to a pluggable instance that implements the **MessageHeadersRelay** interface. A concrete implementation of **MessageHeadersRelay** will be consulted to decide if a header needs to be relayed or not. There is already an implementation of **SoapMessageHeadersRelay** which binds itself to well-known SOAP name spaces. Currently only out-of-band headers are filtered, and in-band headers will always be relayed when **relayHeaders=true**. If there is a header on the wire whose name space is unknown to the runtime, then a fall back **DefaultMessageHeadersRelay** will be used, which simply allows all headers to be relayed.

The **relayHeaders=false** setting specifies that all headers in-band and out-of-band should be dropped.

You can plugin your own **MessageHeadersRelay** implementations overriding or adding additional ones to the list of relays. In order to override a preloaded relay instance just make sure that your **MessageHeadersRelay** implementation services the same name spaces as the one you looking to override. Also note, that the overriding relay has to service all of the name spaces as the one you looking to override, or else a runtime exception on route start up will be thrown as this would introduce an ambiguity in name spaces to relay instance mappings.

```

<cxf:cxfEndpoint ...>
  <cxf:properties>
    <entry key="org.apache.camel.cxf.message.headers.relays">
      <list>
        <ref bean="customHeadersRelay"/>
      </list>
    </entry>
  </cxf:properties>

```

```

</cxf:cxfrEndpoint>
<bean id="customHeadersRelay"
class="org.apache.camel.component.cxf.soap.headers.CustomHeadersRelay"/>

```

Take a look at the tests that show how you'd be able to relay/drop headers here:

<https://github.com/apache/camel/blob/main/components/camel-cxf/camel-cxf-spring-soap/src/test/java/org/apache/camel/component/cxf/soap/headers/CxfMessageHeadersRelayTest.java>

- **POJO** and **PAYLOAD** modes are supported. In **POJO** mode, only out-of-band message headers are available for filtering as the in-band headers have been processed and removed from header list by CXF. The in-band headers are incorporated into the **MessageContentList** in POJO mode. The **camel-cxf** component does make any attempt to remove the in-band headers from the **MessageContentList**. If filtering of in-band headers is required, please use **PAYLOAD** mode or plug in a (pretty straightforward) CXF interceptor/JAXWS Handler to the CXF endpoint.
- The Message Header Relay mechanism has been merged into **CxfHeaderFilterStrategy**. The **relayHeaders** option, its semantics, and default value remain the same, but it is a property of **CxfHeaderFilterStrategy**. Here is an example of configuring it.

```

@Bean
public HeaderFilterStrategy dropAllMessageHeadersStrategy() {
    CxfHeaderFilterStrategy headerFilterStrategy = new CxfHeaderFilterStrategy();
    headerFilterStrategy.setRelayHeaders(false);
    return headerFilterStrategy;
}

```

Then, your endpoint can reference the **CxfHeaderFilterStrategy**.

```

@Bean
public CxfEndpoint routerNoRelayEndpoint(HeaderFilterStrategy dropAllMessageHeadersStrategy) {
    CxfSpringEndpoint cxfEndpoint = new CxfSpringEndpoint();
    cxfEndpoint.setServiceClass(org.apache.camel.component.cxf.soap.headers.HeaderTester.class);
    cxfEndpoint.setAddress("/CxfMessageHeadersRelayTest/HeaderService/routerNoRelayEndpoint");
    cxfEndpoint.setWsdURL("soap_header.wsdl");
    cxfEndpoint.setEndpointNameAsQName(
        QName.valueOf("{http://apache.org/camel/component/cxf/soap/headers}SoapPortNoRelay"));
    cxfEndpoint.setServiceNameAsQName(SERVICENAME);
    Map<String, Object> properties = new HashMap<String, Object>();
    properties.put("dataFormat", "PAYLOAD");
    cxfEndpoint.setProperties(properties);
    cxfEndpoint.setHeaderFilterStrategy(dropAllMessageHeadersStrategy);
    return cxfEndpoint;
}

```

```

@Bean
public CxfEndpoint serviceNoRelayEndpoint(HeaderFilterStrategy dropAllMessageHeadersStrategy)
{
    CxfSpringEndpoint cxfEndpoint = new CxfSpringEndpoint();
    cxfEndpoint.setServiceClass(org.apache.camel.component.cxf.soap.headers.HeaderTester.class);
    cxfEndpoint.setAddress("http://localhost:" + port +
"/services/CxfMessageHeadersRelayTest/HeaderService/routerNoRelayEndpointBackend");
    cxfEndpoint.setWsdURL("soap_header.wsdl");
    cxfEndpoint.setEndpointNameAsQName(

```

```

        QName.valueOf("{http://apache.org/camel/component/cxf/soap/headers}SoapPortNoRelay"));
        cxfEndpoint.setServiceNameAsQName(SERVICENAME);
        Map<String, Object> properties = new HashMap<String, Object>();
        properties.put("dataFormat", "PAYLOAD");
        cxfEndpoint.setProperties(properties);
        cxfEndpoint.setHeaderFilterStrategy(dropAllMessageHeadersStrategy);
        return cxfEndpoint;
    }

```

Then configure the route as follows:

```

from("cxf:bean:routerNoRelayEndpoint")
    .to("cxf:bean:serviceNoRelayEndpoint");

```

- The **MessageHeadersRelay** interface has changed slightly and has been renamed to **MessageHeaderFilter**. It is a property of **CxfHeaderFilterStrategy**. Here is an example of configuring user defined Message Header Filters:

```

@Bean
public HeaderFilterStrategy customMessageFilterStrategy() {
    CxfHeaderFilterStrategy headerFilterStrategy = new CxfHeaderFilterStrategy();
    List<MessageHeaderFilter> headerFilterList = new ArrayList<MessageHeaderFilter>();
    headerFilterList.add(new SoapMessageHeaderFilter());
    headerFilterList.add(new CustomHeaderFilter());
    headerFilterStrategy.setMessageHeaderFilters(headerFilterList);
    return headerFilterStrategy;
}

```

- In addition to **relayHeaders**, the following properties can be configured in **CxfHeaderFilterStrategy**.

Name	Required	Description
relayHeaders	No	All message headers will be processed by Message Header Filters <i>Type: boolean Default: true</i>
relayAllMessageHeaders	No	All message headers will be propagated (without processing by Message Header Filters) <i>Type: boolean Default: false</i>
allowFilterNamespaceClash	No	If two filters overlap in activation namespace, the property control how it should be handled. If the value is true , last one wins. If the value is false , it will throw an exception <i>Type: boolean Default: false</i>

29.6. CONFIGURE THE CXF ENDPOINTS WITH SPRING

You can configure the CXF endpoint with the Spring configuration file shown below, and you can also embed the endpoint into the **camelContext** tags. When you are invoking the service endpoint, you can set the **operationName** and **operationNamespace** headers to explicitly state which operation you are calling.

```

<beans xmlns="http://www.springframework.org/schema/beans"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xmlns:cxf="http://camel.apache.org/schema/cxf/jaxws"
  xsi:schemaLocation="
    http://www.springframework.org/schema/beans
    http://www.springframework.org/schema/beans/spring-beans.xsd
    http://camel.apache.org/schema/cxf/jaxws http://camel.apache.org/schema/cxf/jaxws/camel-
    cxf.xsd
    http://camel.apache.org/schema/spring http://camel.apache.org/schema/spring/camel-
    spring.xsd">
  <cxf:cxfEndpoint id="routerEndpoint" address="http://localhost:9003/CamelContext/RouterPort"
    serviceClass="org.apache.hello_world_soap_http.GreeterImpl"/>
  <cxf:cxfEndpoint id="serviceEndpoint" address="http://localhost:9000/SoapContext/SoapPort"
    wsdlURL="testutils/hello_world.wsdl"
    serviceClass="org.apache.hello_world_soap_http.Greeter"
    endpointName="s:SoapPort"
    serviceName="s:SOAPService"
    xmlns:s="http://apache.org/hello_world_soap_http" />
  <camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
    <route>
      <from uri="cxf:bean:routerEndpoint" />
      <to uri="cxf:bean:serviceEndpoint" />
    </route>
  </camelContext>
</beans>

```

Be sure to include the JAX-WS **schemaLocation** attribute specified on the root beans element. This allows CXF to validate the file and is required. Also note the namespace declarations at the end of the **<cxf:cxfEndpoint/>** tag. These declarations are required because the combined **{namespace}localName** syntax is presently not supported for this tag's attribute values.

The **cxf:cxfEndpoint** element supports many additional attributes:

Name	Value
PortName	The endpoint name this service is implementing, it maps to the wsdl:port@name . In the format of ns:PORT_NAME where ns is a namespace prefix valid at this scope.
serviceName	The service name this service is implementing, it maps to the wsdl:service@name . In the format of ns:SERVICE_NAME where ns is a namespace prefix valid at this scope.
wsdlURL	The location of the WSDL. Can be on the classpath, file system, or be hosted remotely.
bindingId	The bindingId for the service model to use.
address	The service publish address.
bus	The bus name that will be used in the JAX-WS endpoint.

Name	Value
serviceClass	The class name of the SEI (Service Endpoint Interface) class which could have JSR181 annotation or not.

It also supports many child elements:

Name	Value
cxf:inInterceptors	The incoming interceptors for this endpoint. A list of <bean> or <ref> .
cxf:inFaultInterceptors	The incoming fault interceptors for this endpoint. A list of <bean> or <ref> .
cxf:outInterceptors	The outgoing interceptors for this endpoint. A list of <bean> or <ref> .
cxf:outFaultInterceptors	The outgoing fault interceptors for this endpoint. A list of <bean> or <ref> .
cxf:properties	A properties map which should be supplied to the JAX-WS endpoint. See below.
cxf:handlers	A JAX-WS handler list which should be supplied to the JAX-WS endpoint. See below.
cxf:dataBinding	You can specify the which DataBinding will be use in the endpoint. This can be supplied using the Spring <bean class="MyDataBinding"/> syntax.
cxf:binding	You can specify the BindingFactory for this endpoint to use. This can be supplied using the Spring <bean class="MyBindingFactory"/> syntax.
cxf:features	The features that hold the interceptors for this endpoint. A list of beans or refs
cxf:schemaLocations	The schema locations for endpoint to use. A list of schemaLocations
cxf:serviceFactory	The service factory for this endpoint to use. This can be supplied using the Spring <bean class="MyServiceFactory"/> syntax

You can find more advanced examples that show how to provide interceptors, properties and handlers on the CXF [JAX-WS Configuration page](#).

NOTE

You can use `cxf:properties` to set the camel-cxf endpoint's `dataFormat` and `setDefaultBus` properties from spring configuration file.

```
<cxf:cxfEndpoint id="testEndpoint" address="http://localhost:9000/router"
  serviceClass="org.apache.camel.component.cxf.HelloService"
  endpointName="s:PortName"
  serviceName="s:ServiceName"
  xmlns:s="http://www.example.com/test">
  <cxf:properties>
    <entry key="dataFormat" value="RAW"/>
    <entry key="setDefaultBus" value="true"/>
  </cxf:properties>
</cxf:cxfEndpoint>
```

NOTE

In SpringBoot, you can use Spring XML files to configure **camel-cxf** and use code similar to the following example to create XML configured beans:

```
@ImportResource({
  "classpath:spring-configuration.xml"
})
```

However, the use of Java code configured beans (as shown in other examples) is best practice in SpringBoot.

29.7. HOW TO MAKE THE CAMEL-CXF COMPONENT USE LOG4J INSTEAD OF JAVA.UTIL.LOGGING

CXF's default logger is **java.util.logging**. If you want to change it to log4j, proceed as follows. Create a file, in the classpath, named **META-INF/cxf/org.apache.cxf.logger**. This file should contain the fully-qualified name of the class, **org.apache.cxf.common.logging.Log4jLogger**, with no comments, on a single line.

29.8. HOW TO LET CAMEL-CXF RESPONSE START WITH XML PROCESSING INSTRUCTION

If you are using some SOAP client such as PHP, you will get this kind of error, because CXF doesn't add the XML processing instruction **<?xml version="1.0" encoding="utf-8"?>**:

```
Error:sendSms: SoapFault exception: [Client] looks like we got no XML document in [...]
```

To resolve this issue, you just need to tell `StaxOutInterceptor` to write the XML start document for you, as in the [WriteXmlDeclarationInterceptor](#) below:

```
public class WriteXmlDeclarationInterceptor extends AbstractPhaseInterceptor<SoapMessage> {
  public WriteXmlDeclarationInterceptor() {
    super(Phase.PRE_STREAM);
    addBefore(StaxOutInterceptor.class.getName());
  }
}
```

```

    public void handleMessage(SoapMessage message) throws Fault {
        message.put("org.apache.cxf.stax.force-start-document", Boolean.TRUE);
    }
}

```

As an alternative you can add a message header for it as demonstrated in [CxfConsumerTest](#):

```

// set up the response context which force start document
Map<String, Object> map = new HashMap<String, Object>();
map.put("org.apache.cxf.stax.force-start-document", Boolean.TRUE);
exchange.getOut().setHeader(Client.RESPONSE_CONTEXT, map);

```

29.9. HOW TO OVERRIDE THE CXF PRODUCER ADDRESS FROM MESSAGE HEADER

The **camel-cxf** producer supports to override the target service address by setting a message header **CamelDestinationOverrideUrl**.

```

// set up the service address from the message header to override the setting of CXF endpoint
exchange.getIn().setHeader(Exchange.DESTINATION_OVERRIDE_URL,
    constant(getServiceAddress()));

```

29.10. HOW TO CONSUME A MESSAGE FROM A CAMEL-CXF ENDPOINT IN POJO DATA FORMAT

The **camel-cxf** endpoint consumer POJO data format is based on the [CXF invoker](#), so the message header has a property with the name of **CxfConstants.OPERATION_NAME** and the message body is a list of the SEI method parameters.

Consider the [PersonProcessor](#) example code:

```

public class PersonProcessor implements Processor {

    private static final Logger LOG = LoggerFactory.getLogger(PersonProcessor.class);

    @Override
    @SuppressWarnings("unchecked")
    public void process(Exchange exchange) throws Exception {
        LOG.info("processing exchange in camel");

        BindingOperationInfo boi = (BindingOperationInfo)
exchange.getProperty(BindingOperationInfo.class.getName());
        if (boi != null) {
            LOG.info("boi.isUnwrapped" + boi.isUnwrapped());
        }
        // Get the parameters list which element is the holder.
        MessageContentsList msgList = (MessageContentsList) exchange.getIn().getBody();
        Holder<String> personId = (Holder<String>) msgList.get(0);
        Holder<String> ssn = (Holder<String>) msgList.get(1);
        Holder<String> name = (Holder<String>) msgList.get(2);
    }
}

```

```

        if (personId.value == null || personId.value.length() == 0) {
            LOG.info("person id 123, so throwing exception");
            // Try to throw out the soap fault message
            org.apache.camel.wsdl_first.types.UnknownPersonFault personFault
                = new org.apache.camel.wsdl_first.types.UnknownPersonFault();
            personFault.setPersonId("");
            org.apache.camel.wsdl_first.UnknownPersonFault fault
                = new org.apache.camel.wsdl_first.UnknownPersonFault("Get the null value of person
name", personFault);
            exchange.getMessage().setBody(fault);
            return;
        }

        name.value = "Bonjour";
        ssn.value = "123";
        LOG.info("setting Bonjour as the response");
        // Set the response message, first element is the return value of the operation,
        // the others are the holders of method parameters
        exchange.getMessage().setBody(new Object[] { null, personId, ssn, name });
    }
}

```

29.11. HOW TO PREPARE THE MESSAGE FOR THE CAMEL-CXF ENDPOINT IN POJO DATA FORMAT

The **camel-cxf** endpoint producer is based on the [CXF client API](#). First you need to specify the operation name in the message header, then add the method parameters to a list, and initialize the message with this parameter list. The response message's body is a `messageContentsList`, you can get the result from that list.

If you don't specify the operation name in the message header, **CxfProducer** will try to use the **defaultOperationName** from **CxfEndpoint**, if there is no **defaultOperationName** set on **CxfEndpoint**, it will pick up the first `operationName` from the `Operation` list.

If you want to get the object array from the message body, you can get the body using **message.getBody(Object[].class)**, as shown in [CxfProducerRouterTest.testInvokingSimpleServerWithParams](#):

```

Exchange senderExchange = new DefaultExchange(context, ExchangePattern.InOut);
final List<String> params = new ArrayList<>();
// Prepare the request message for the camel-cxf procedure
params.add(TEST_MESSAGE);
senderExchange.getIn().setBody(params);
senderExchange.getIn().setHeader(CxfConstants.OPERATION_NAME, ECHO_OPERATION);

Exchange exchange = template.send("direct:EndpointA", senderExchange);

org.apache.camel.Message out = exchange.getMessage();
// The response message's body is an MessageContentsList which first element is the return value of
the operation,
// If there are some holder parameters, the holder parameter will be filled in the rest of List.
// The result will be extract from the MessageContentsList with the String class type
MessageContentsList result = (MessageContentsList) out.getBody();
LOG.info("Received output text: " + result.get(0));

```

```

Map<String, Object> responseContext = CastUtils.cast((Map<?, ?>)
out.getHeader(Client.RESPONSE_CONTEXT));
assertNotNull(responseContext);
assertEquals("UTF-8", responseContext.get(org.apache.cxf.message.Message.ENCODING),
    "We should get the response context here");
assertEquals("echo " + TEST_MESSAGE, result.get(0), "Reply body on Camel is wrong");

```

29.12. HOW TO DEAL WITH THE MESSAGE FOR A CAMEL-CXF ENDPOINT IN PAYLOAD DATA FORMAT

PAYLOAD means that you process the payload from the SOAP envelope as a native `CxfPayload`.

Message.getBody() will return a **org.apache.camel.component.cxf.CxfPayload** object, with getters for SOAP message headers and the SOAP body.

See [CxfConsumerPayloadTest](#):

```

protected RouteBuilder createRouteBuilder() {
    return new RouteBuilder() {
        public void configure() {
            from(simpleEndpointURI + "&dataFormat=PAYLOAD").to("log:info").process(new Processor()
{
    @SuppressWarnings("unchecked")
    public void process(final Exchange exchange) throws Exception {
        CxfPayload<SoapHeader> requestPayload =
exchange.getIn().getBody(CxfPayload.class);
        List<Source> inElements = requestPayload.getBodySources();
        List<Source> outElements = new ArrayList<>();
        // You can use a customer toStringConverter to turn a CxfPayload message into String
as you want
        String request = exchange.getIn().getBody(String.class);
        XmlConverter converter = new XmlConverter();
        String documentString = ECHO_RESPONSE;

        Element in = new XmlConverter().toDOMElement(inElements.get(0));
        // Just check the element namespace
        if (!in.getNamespaceURI().equals(ELEMENT_NAMESPACE)) {
            throw new IllegalArgumentException("Wrong element namespace");
        }
        if (in.getLocalName().equals("echoBoolean")) {
            documentString = ECHO_BOOLEAN_RESPONSE;
            checkRequest("ECHO_BOOLEAN_REQUEST", request);
        } else {
            documentString = ECHO_RESPONSE;
            checkRequest("ECHO_REQUEST", request);
        }
        Document outDocument = converter.toDOMDocument(documentString, exchange);
        outElements.add(new DOMSource(outDocument.getDocumentElement()));
        // set the payload header with null
        CxfPayload<SoapHeader> responsePayload = new CxfPayload<>(null, outElements,
null);

        exchange.getMessage().setBody(responsePayload);
    }
});
}

```

```

    }
  };
}

```

29.13. HOW TO GET AND SET SOAP HEADERS IN POJO MODE

POJO means that the data format is a "list of Java objects" when the camel-cxf endpoint produces or consumes Camel exchanges. Even though Camel exposes the message body as POJOs in this mode, camel-cxf still provides access to read and write SOAP headers. However, since CXF interceptors remove in-band SOAP headers from the header list after they have been processed, only out-of-band SOAP headers are available to camel-cxf in POJO mode.

The following example illustrates how to get/set SOAP headers. Suppose we have a route that forwards from one Camel-cxf endpoint to another. That is, SOAP Client → Camel → CXF service. We can attach two processors to obtain/insert SOAP headers at (1) before a request goes out to the CXF service and (2) before the response comes back to the SOAP Client. Processor (1) and (2) in this example are `InsertRequestOutHeaderProcessor` and `InsertResponseOutHeaderProcessor`. Our route looks like this:

```

from("cxf:bean:routerRelayEndpointWithInsertion")
  .process(new InsertRequestOutHeaderProcessor())
  .to("cxf:bean:serviceRelayEndpointWithInsertion")
  .process(new InsertResponseOutHeaderProcessor());

```

The Bean **`routerRelayEndpointWithInsertion`** and **`serviceRelayEndpointWithInsertion`** are defined as follows:

```

@Bean
public CxfEndpoint routerRelayEndpointWithInsertion() {
    CxfSpringEndpoint cxfEndpoint = new CxfSpringEndpoint();
    cxfEndpoint.setServiceClass(org.apache.camel.component.cxf.soap.headers.HeaderTester.class);

    cxfEndpoint.setAddress("/CxfMessageHeadersRelayTest/HeaderService/routerRelayEndpointWithInsertion");
    cxfEndpoint.setWsdIURL("soap_header.wsdl");
    cxfEndpoint.setEndpointNameAsQName(
        QName.valueOf("
{http://apache.org/camel/component/cxf/soap/headers}SoapPortRelayWithInsertion"));
    cxfEndpoint.setServiceNameAsQName(SERVICENAME);
    cxfEndpoint.getFeatures().add(new LoggingFeature());
    return cxfEndpoint;
}

@Bean
public CxfEndpoint serviceRelayEndpointWithInsertion() {
    CxfSpringEndpoint cxfEndpoint = new CxfSpringEndpoint();
    cxfEndpoint.setServiceClass(org.apache.camel.component.cxf.soap.headers.HeaderTester.class);
    cxfEndpoint.setAddress("http://localhost:" + port +
"/services/CxfMessageHeadersRelayTest/HeaderService/routerRelayEndpointWithInsertionBackend");

    cxfEndpoint.setWsdIURL("soap_header.wsdl");
    cxfEndpoint.setEndpointNameAsQName(
        QName.valueOf("
{http://apache.org/camel/component/cxf/soap/headers}SoapPortRelayWithInsertion"));
    cxfEndpoint.setServiceNameAsQName(SERVICENAME);

```

```

    cxfEndpoint.getFeatures().add(new LoggingFeature());
    return cxfEndpoint;
}

```

SOAP headers are propagated to and from Camel Message headers. The Camel message header name is "org.apache.cxf.headers.Header.list" which is a constant defined in CXF (org.apache.cxf.headers.Header.HEADER_LIST). The header value is a List of CXF SoapHeader objects (org.apache.cxf.binding.soap.SoapHeader). The following snippet is the InsertResponseOutHeaderProcessor (that insert a new SOAP header in the response message). The way to access SOAP headers in both InsertResponseOutHeaderProcessor and InsertRequestOutHeaderProcessor are actually the same. The only difference between the two processors is setting the direction of the inserted SOAP header.

You can find the **InsertResponseOutHeaderProcessor** example in [CxfMessageHeadersRelayTest](#):

```

public static class InsertResponseOutHeaderProcessor implements Processor {

    public void process(Exchange exchange) throws Exception {
        List<SoapHeader> soapHeaders = CastUtils.cast((List<?
>)exchange.getIn().getHeader(Header.HEADER_LIST));

        // Insert a new header
        String xml = "<?xml version=\"1.0\" encoding=\"utf-8\"?><outofbandHeader "
            + "xmlns=\"http://cxf.apache.org/outofband/Header\" hdrAttribute=\"testHdrAttribute\" "
            + "xmlns:soap=\"http://schemas.xmlsoap.org/soap/envelope/\" soap:mustUnderstand=\"1\">"
            + "<name>New_testOobHeader</name><value>New_testOobHeaderValue</value>"
        </outofbandHeader>";
        SoapHeader newHeader = new SoapHeader(soapHeaders.get(0).getName(),
            DOMUtils.readXml(new StringReader(xml)).getDocumentElement());
        // make sure direction is OUT since it is a response message.
        newHeader.setDirection(Direction.DIRECTION_OUT);
        //newHeader.setMustUnderstand(false);
        soapHeaders.add(newHeader);
    }
}

```

29.14. HOW TO GET AND SET SOAP HEADERS IN PAYLOAD MODE

We've already shown how to access the SOAP message as CxfPayload object in PAYLOAD mode in the section [How to deal with the message for a camel-cxf endpoint in PAYLOAD data format](#) .

Once you obtain a CxfPayload object, you can invoke the CxfPayload.getHeaders() method that returns a List of DOM Elements (SOAP headers).

For an example see [CxfPayloadSoapHeaderTest](#):

```

from(getRouterEndpointURI()).process(new Processor() {
    @SuppressWarnings("unchecked")
    public void process(Exchange exchange) throws Exception {
        CxfPayload<SoapHeader> payload = exchange.getIn().getBody(CxfPayload.class);
        List<Source> elements = payload.getBodySources();
        assertNotNull(elements, "We should get the elements here");
        assertEquals(1, elements.size(), "Get the wrong elements size");
    }
}

```

```

Element el = new XmlConverter().toDOMElement(elements.get(0));
elements.set(0, new DOMSource(el));
assertEquals("http://camel.apache.org/pizza/types",
    el.getNamespaceURI(), "Get the wrong namespace URI");

List<SoapHeader> headers = payload.getHeaders();
assertNotNull(headers, "We should get the headers here");
assertEquals(1, headers.size(), "Get the wrong headers size");
assertEquals("http://camel.apache.org/pizza/types",
    ((Element) (headers.get(0).getObject())).getNamespaceURI(), "Get the wrong namespace
URI");
// alternatively you can also get the SOAP header via the camel header:
headers = exchange.getIn().getHeader(Header.HEADER_LIST, List.class);
assertNotNull(headers, "We should get the headers here");
assertEquals(1, headers.size(), "Get the wrong headers size");
assertEquals("http://camel.apache.org/pizza/types",
    ((Element) (headers.get(0).getObject())).getNamespaceURI(), "Get the wrong namespace
URI");
}

})
.to(getServiceEndpointURI());

```

You can also use the same way as described in sub-chapter "How to get and set SOAP headers in POJO mode" to set or get the SOAP headers. So, you can use the header "org.apache.cxf.headers.Header.list" to get and set a list of SOAP headers. This does also mean that if you have a route that forwards from one Camel-cxf endpoint to another (SOAP Client → Camel → CXF service), now also the SOAP headers sent by the SOAP client are forwarded to the CXF service. If you do not want that these headers are forwarded you have to remove them in the Camel header "org.apache.cxf.headers.Header.list".

29.15. SOAP HEADERS ARE NOT AVAILABLE IN RAW MODE

SOAP headers are not available in RAW mode as SOAP processing is skipped.

29.16. HOW TO THROW A SOAP FAULT FROM CAMEL

If you are using a **camel-cxf** endpoint to consume the SOAP request, you may need to throw the SOAP Fault from the camel context.

Basically, you can use the **throwFault** DSL to do that; it works for **POJO**, **PAYLOAD** and **MESSAGE** data format.

You can define the soap fault as shown in [CxfCustomizedExceptionTest](#):

```

SOAP_FAULT = new SoapFault(EXCEPTION_MESSAGE, SoapFault.FAULT_CODE_CLIENT);
Element detail = SOAP_FAULT.getOrCreateDetail();
Document doc = detail.getOwnerDocument();
Text tn = doc.createTextNode(DETAIL_TEXT);
detail.appendChild(tn);

```

Then throw it as you like

```

from(routerEndpointURI).setFaultBody(constant(SOAP_FAULT));

```

If your CXF endpoint is working in the **MESSAGE** data format, you could set the SOAP Fault message in the message body and set the response code in the message header as demonstrated by [CxfMessageStreamExceptionTest](#)

```
from(routerEndpointURI).process(new Processor() {

    public void process(Exchange exchange) throws Exception {
        Message out = exchange.getOut();
        // Set the message body with the
        out.setBody(this.getClass().getResourceAsStream("SoapFaultMessage.xml"));
        // Set the response code here
        out.setHeader(org.apache.cxf.message.Message.RESPONSE_CODE, new Integer(500));
    }

});
```

Same for using POJO data format. You can set the SOAPFault on the out body.

29.17. HOW TO PROPAGATE A CAMEL-CXF ENDPOINT'S REQUEST AND RESPONSE CONTEXT

[CXF client API](#) provides a way to invoke the operation with request and response context. If you are using a **camel-cxf** endpoint producer to invoke the outside web service, you can set the request context and get response context with the following code:

```
CxfExchange exchange = (CxfExchange)template.send(getJaxwsEndpointUri(), new
Processor() {
    public void process(final Exchange exchange) {
        final List<String> params = new ArrayList<String>();
        params.add(TEST_MESSAGE);
        // Set the request context to the inMessage
        Map<String, Object> requestContext = new HashMap<String, Object>();
        requestContext.put(BindingProvider.ENDPOINT_ADDRESS_PROPERTY,
JAXWS_SERVER_ADDRESS);
        exchange.getIn().setBody(params);
        exchange.getIn().setHeader(Client.REQUEST_CONTEXT, requestContext);
        exchange.getIn().setHeader(CxfConstants.OPERATION_NAME,
GREET_ME_OPERATION);
    }
});
org.apache.camel.Message out = exchange.getOut();
// The output is an object array, the first element of the array is the return value
Object[] output = out.getBody(Object[].class);
LOG.info("Received output text: " + output[0]);
// Get the response context form outMessage
Map<String, Object> responseContext =
CastUtils.cast((Map)out.getHeader(Client.RESPONSE_CONTEXT));
assertNotNull(responseContext);
assertEquals("Get the wrong wsdl operation name", "
{http://apache.org/hello_world_soap_http}greetMe",
    responseContext.get("javax.xml.ws.wsdl.operation").toString());
```

29.18. ATTACHMENT SUPPORT

POJO Mode: Both SOAP with Attachment and MTOM are supported (see example in Payload Mode for enabling MTOM). However, SOAP with Attachment is not tested. Since attachments are marshalled and unmarshalled into POJOs, users typically do not need to deal with the attachment themselves. Attachments are propagated to Camel message's attachments if the MTOM is not enabled. So, it is possible to retrieve attachments by Camel Message API

```
DataHandler Message.getAttachment(String id)
```

Payload Mode: MTOM is supported by the component. Attachments can be retrieved by Camel Message APIs mentioned above. SOAP with Attachment (SwA) is supported and attachments can be retrieved. SwA is the default (same as setting the CXF endpoint property "mtom-enabled" to false).

To enable MTOM, set the CXF endpoint property "mtom-enabled" to *true*.

```
@Bean
public CxfEndpoint routerEndpoint() {
    CxfSpringEndpoint cxfEndpoint = new CxfSpringEndpoint();
    cxfEndpoint.setServiceNameAsQName(SERVICE_QNAME);
    cxfEndpoint.setEndpointNameAsQName(PORT_QNAME);
    cxfEndpoint.setAddress("/") + getClass().getSimpleName() + "/jaxws-mtom/hello");
    cxfEndpoint.setWsdURL("mtom.wsdl");
    Map<String, Object> properties = new HashMap<String, Object>();
    properties.put("dataFormat", "PAYLOAD");
    properties.put("mtom-enabled", true);
    cxfEndpoint.setProperties(properties);
    return cxfEndpoint;
}
```

You can produce a Camel message with attachment to send to a CXF endpoint in Payload mode.

```
Exchange exchange = context.createProducerTemplate().send("direct:testEndpoint", new
Processor() {

    public void process(Exchange exchange) throws Exception {
        exchange.setPattern(ExchangePattern.InOut);
        List<Source> elements = new ArrayList<Source>();
        elements.add(new DOMSource(DOMUtils.readXml(new
StringReader(MtomTestHelper.REQ_MESSAGE)).getDocumentElement()));
        CxfPayload<SoapHeader> body = new CxfPayload<SoapHeader>(new ArrayList<SoapHeader>
()),
            elements, null);
        exchange.getIn().setBody(body);
        exchange.getIn().addAttachment(MtomTestHelper.REQ_PHOTO_CID,
            new DataHandler(new ByteArrayDataSource(MtomTestHelper.REQ_PHOTO_DATA,
"application/octet-stream")));

        exchange.getIn().addAttachment(MtomTestHelper.REQ_IMAGE_CID,
            new DataHandler(new ByteArrayDataSource(MtomTestHelper.requestJpeg, "image/jpeg")));
    }

});

// process response
```

```

CxfPayload<SoapHeader> out = exchange.getOut().getBody(CxfPayload.class);
Assert.assertEquals(1, out.getBody().size());

Map<String, String> ns = new HashMap<String, String>();
ns.put("ns", MtomTestHelper.SERVICE_TYPES_NS);
ns.put("xop", MtomTestHelper.XOP_NS);

XPathUtils xu = new XPathUtils(ns);
Element oute = new XmlConverter().toDOMElement(out.getBody().get(0));
Element ele = (Element)xu.getValue("//ns:DetailResponse/ns:photo/xop:Include", oute,
    XPathConstants.NODE);
String photold = ele.getAttribute("href").substring(4); // skip "cid:"

ele = (Element)xu.getValue("//ns:DetailResponse/ns:image/xop:Include", oute,
    XPathConstants.NODE);
String imageld = ele.getAttribute("href").substring(4); // skip "cid:"

DataHandler dr = exchange.getOut().getAttachment(photold);
Assert.assertEquals("application/octet-stream", dr.getContentType());
MtomTestHelper.assertEquals(MtomTestHelper.RESP_PHOTO_DATA,
    IOUtils.readBytesFromStream(dr.getInputStream()));

dr = exchange.getOut().getAttachment(imageld);
Assert.assertEquals("image/jpeg", dr.getContentType());

BufferedImage image = ImageIO.read(dr.getInputStream());
Assert.assertEquals(560, image.getWidth());
Assert.assertEquals(300, image.getHeight());

```

You can also consume a Camel message received from a CXF endpoint in Payload mode. The [CxfMtomConsumerPayloadModeTest](#) illustrates how this works:

```

public static class MyProcessor implements Processor {

    @SuppressWarnings("unchecked")
    public void process(Exchange exchange) throws Exception {
        CxfPayload<SoapHeader> in = exchange.getIn().getBody(CxfPayload.class);

        // verify request
        Assert.assertEquals(1, in.getBody().size());

        Map<String, String> ns = new HashMap<String, String>();
        ns.put("ns", MtomTestHelper.SERVICE_TYPES_NS);
        ns.put("xop", MtomTestHelper.XOP_NS);

        XPathUtils xu = new XPathUtils(ns);
        Element body = new XmlConverter().toDOMElement(in.getBody().get(0));
        Element ele = (Element)xu.getValue("//ns:Detail/ns:photo/xop:Include", body,
            XPathConstants.NODE);
        String photold = ele.getAttribute("href").substring(4); // skip "cid:"
        Assert.assertEquals(MtomTestHelper.REQ_PHOTO_CID, photold);

        ele = (Element)xu.getValue("//ns:Detail/ns:image/xop:Include", body,
            XPathConstants.NODE);
        String imageld = ele.getAttribute("href").substring(4); // skip "cid:"
        Assert.assertEquals(MtomTestHelper.REQ_IMAGE_CID, imageld);
    }
}

```

```

        DataHandler dr = exchange.getIn().getAttachment(photoid);
        Assert.assertEquals("application/octet-stream", dr.getContentType());
        MtomTestHelper.assertEquals(MtomTestHelper.REQ_PHOTO_DATA,
        IOUtils.readBytesFromStream(dr.getInputStream()));

        dr = exchange.getIn().getAttachment(imageld);
        Assert.assertEquals("image/jpeg", dr.getContentType());
        MtomTestHelper.assertEquals(MtomTestHelper.requestJpeg,
        IOUtils.readBytesFromStream(dr.getInputStream()));

        // create response
        List<Source> elements = new ArrayList<Source>();
        elements.add(new DOMSource(DOMUtils.readXml(new
        StringReader(MtomTestHelper.RESP_MESSAGE)).getDocumentElement()));
        CxfPayload<SoapHeader> sbody = new CxfPayload<SoapHeader>(new
        ArrayList<SoapHeader>(),
            elements, null);
        exchange.getOut().setBody(sbody);
        exchange.getOut().addAttachment(MtomTestHelper.RESP_PHOTO_CID,
            new DataHandler(new ByteArrayDataSource(MtomTestHelper.RESP_PHOTO_DATA,
            "application/octet-stream")));

        exchange.getOut().addAttachment(MtomTestHelper.RESP_IMAGE_CID,
            new DataHandler(new ByteArrayDataSource(MtomTestHelper.responseJpeg, "image/jpeg")));
    }
}

```

Raw Mode: Attachments are not supported as it does not process the message at all.

CXF_RAW Mode: MTOM is supported, and Attachments can be retrieved by Camel Message APIs mentioned above. Note that when receiving a multipart (i.e. MTOM) message the default SOAPMessage to String converter will provide the complete multipart payload on the body. If you require just the SOAP XML as a String, you can set the message body with `message.getSOAPPart()`, and Camel convert can do the rest of work for you.

29.19. STREAMING SUPPORT IN PAYLOAD MODE

The camel-cxf component now supports streaming of incoming messages when using PAYLOAD mode. Previously, the incoming messages would have been completely DOM parsed. For large messages, this is time consuming and uses a significant amount of memory. The incoming messages can remain as a `javax.xml.transform.Source` while being routed and, if nothing modifies the payload, can then be directly streamed out to the target destination. For common "simple proxy" use cases (example: `from("cxf:...").to("cxf:...")`), this can provide very significant performance increases as well as significantly lowered memory requirements.

However, there are cases where streaming may not be appropriate or desired. Due to the streaming nature, invalid incoming XML may not be caught until later in the processing chain. Also, certain actions may require the message to be DOM parsed anyway (like WS-Security or message tracing and such) in which case the advantages of the streaming is limited. At this point, there are two ways to control the streaming:

- Endpoint property: you can add `"allowStreaming=false"` as an endpoint property to turn the streaming on/off.

- Component property: the CxfComponent object also has an allowStreaming property that can set the default for endpoints created from that component.

Global system property: you can add a system property of "org.apache.camel.component.cxf.streaming" to "false" to turn it off. That sets the global default, but setting the endpoint property above will override this value for that endpoint.

29.20. USING THE GENERIC CXF DISPATCH MODE

The camel-cxf component supports the generic [CXF dispatch mode](#) that can transport messages of arbitrary structures (i.e., not bound to a specific XML schema). To use this mode, you simply omit specifying the wsdlURL and serviceClass attributes of the CXF endpoint.

```
<cxf:cxfEndpoint id="testEndpoint" address="http://localhost:9000/SoapContext/SoapAnyPort">
  <cxf:properties>
    <entry key="dataFormat" value="PAYLOAD"/>
  </cxf:properties>
</cxf:cxfEndpoint>
```

It is noted that the default CXF dispatch client does not send a specific SOAPAction header. Therefore, when the target service requires a specific SOAPAction value, it is supplied in the Camel header using the key SOAPAction (case-insensitive).

29.21. SPRING BOOT AUTO-CONFIGURATION

The component supports 13 options, which are listed below.

Name	Description	Default	Type
camel.component.cxf.allow-streaming	This option controls whether the CXF component, when running in PAYLOAD mode, will DOM parse the incoming messages into DOM Elements or keep the payload as a javax.xml.transform.Source object that would allow streaming in some cases.		Boolean
camel.component.cxf.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.cxf.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.cxf.enabled	Whether to enable auto configuration of the cxf component. This is enabled by default.		Boolean
camel.component.cxf.header-filter-strategy	To use a custom <code>org.apache.camel.spi.HeaderFilterStrategy</code> to filter header to and from Camel message. The option is a <code>org.apache.camel.spi.HeaderFilterStrategy</code> type.		HeaderFilterStrategy
camel.component.cxf.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.cxf.use-global-ssl-context-parameters	Enable usage of global SSL context parameters.	false	Boolean
camel.component.cxf.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.cxfrcs.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.cxfrcs.enabled	Whether to enable auto configuration of the cxfrcs component. This is enabled by default.		Boolean
camel.component.cxfrcs.header-filter-strategy	To use a custom <code>org.apache.camel.spi.HeaderFilterStrategy</code> to filter header to and from Camel message. The option is a <code>org.apache.camel.spi.HeaderFilterStrategy</code> type.		HeaderFilterStrategy
camel.component.cxfrcs.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.cxfrcs.use-global-ssl-context-parameters	Enable usage of global SSL context parameters.	false	Boolean

CHAPTER 30. CXF-RS

Both producer and consumer are supported

The CXFRS component provides integration with [Apache CXF](#) for connecting to JAX-RS 1.1 and 2.0 services hosted in CXF.

30.1. DEPENDENCIES

When using **camel-cxf-rest** with Red Hat build of Camel Spring Boot, add the following Maven dependency to your **pom.xml** to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-cxf-rest-starter</artifactId>
</dependency>
```

30.2. URI FORMAT

```
cxfrs://address?options
```

Where the **address** represents the address of the CXF endpoint.

```
cxfrs:bean:rsEndpoint
```

Where the **rsEndpoint** represents the name of the spring bean, which presents the CXFRS client or server.

For the formats above, you can append options to the URI as follows:

```
cxfrs:bean:cxfrEndpoint?resourceClasses=org.apache.camel.rs.Example
```

30.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

30.3.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).

- in a configuration file (application.properties, *.yaml files, etc).
- directly in the Java code.

30.3.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

30.4. COMPONENT OPTIONS

The CXF-RS component supports 5 options, which are listed below.

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions (if possible) occurred while the Camel consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. Important: This is only possible if the 3rd party component allows Camel to be alerted if an exception was thrown. Some components handle this internally only, and therefore bridgeErrorHandler is not possible. In other situations we may improve the Camel component to hook into the 3rd party component and make this possible for future releases. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
headerFilterStrategy (filter)	To use a custom org.apache.camel.spi.HeaderFilterStrategy to filter header to and from Camel message.		HeaderFilterStrategy
useGlobalSslContextParameters (security)	Enable usage of global SSL context parameters.	false	boolean

30.5. ENDPOINT OPTIONS

The CXF-RS endpoint is configured using URI syntax:

```
cxfrs:beanId:address
```

With the following *path* and *query* parameters:

30.5.1. Path Parameters (2 parameters)

Name	Description	Default	Type
beanId (common)	To lookup an existing configured CxfRsEndpoint. Must use bean: as prefix.		String
address (common)	The service publish address.		String

30.5.2. Query Parameters (31 parameters)

Name	Description	Default	Type
features (common)	Set the feature list to the CxfRs endpoint.		List
loggingFeatureEnabled (common)	This option enables CXF Logging Feature which writes inbound and outbound REST messages to log.	false	boolean
loggingSizeLimit (common)	To limit the total size of number of bytes the logger will output when logging feature has been enabled.		int
modelRef (common)	This option is used to specify the model file which is useful for the resource class without annotation. When using this option, then the service class can be omitted, to emulate document-only endpoints.		String
providers (common)	Set custom JAX-RS provider(s) list to the CxfRs endpoint. You can specify a string with a list of providers to lookup in the registry separated by comma.		String
resourceClasses (common)	The resource classes which you want to export as REST service. Multiple classes can be separated by comma.		List
schemaLocations (common)	Sets the locations of the schema(s) which can be used to validate the incoming XML or JAXB-driven JSON.		List
skipFaultLogging (common)	This option controls whether the PhaseInterceptorChain skips logging the Fault that it catches.	false	boolean

Name	Description	Default	Type
bindingStyle (consumer)	Sets how requests and responses will be mapped to/from Camel. Two values are possible: SimpleConsumer: This binding style processes request parameters, multipart, etc. and maps them to IN headers, IN attachments and to the message body. It aims to eliminate low-level processing of <code>org.apache.cxf.message.MessageContentsList</code>. It also adds more flexibility and simplicity to the response mapping. Only available for consumers. Default: The default style. For consumers this passes on a <code>MessageContentsList</code> to the route, requiring low-level processing in the route. This is the traditional binding style, which simply dumps the <code>org.apache.cxf.message.MessageContentsList</code> coming in from the CXF stack onto the IN message body. The user is then responsible for processing it according to the contract defined by the JAX-RS method signature. Custom: allows you to specify a custom binding through the binding option. Enum values: ● SimpleConsumer ● Default ● Custom	Default	BindingStyle
publishedEndpointUrl (consumer)	This option can override the <code>endpointUrl</code> that published from the WADL which can be accessed with resource address url plus <code>_wadl</code> .		String
bridgeErrorHandler (consumer (advanced))	Allows for bridging the consumer to the Camel routing Error Handler, which means any exceptions (if possible) occurred while the Camel consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. Important: This is only possible if the 3rd party component allows Camel to be alerted if an exception was thrown. Some components handle this internally only, and therefore <code>bridgeErrorHandler</code> is not possible. In other situations we may improve the Camel component to hook into the 3rd party component and make this possible for future releases. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean

Name	Description	Default	Type
exceptionHandler (consumer (advanced))	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		<code>ExceptionHandler</code>
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • <code>InOnly</code> • <code>InOut</code>		<code>ExchangePattern</code>
serviceBeans (consumer (advanced))	The service beans (the bean ids to lookup in the registry) which you want to export as REST service. Multiple beans can be separated by comma.		<code>String</code>
cookieHandler (producer)	Configure a cookie handler to maintain a HTTP session.		<code>CookieHandler</code>
hostnameVerifier (producer)	The hostname verifier to be used. Use the <code>#</code> notation to reference a <code>HostnameVerifier</code> from the registry.		<code>HostnameVerifier</code>
sslContextParameters (producer)	The Camel SSL setting reference. Use the <code>#</code> notation to reference the SSL Context.		<code>SSLContextParameters</code>
throwExceptionOnFailure (producer)	This option tells the <code>CxfRsProducer</code> to inspect return codes and will generate an <code>Exception</code> if the return code is larger than 207.	<code>true</code>	<code>boolean</code>
httpClientAPI (producer (advanced))	If it is true, the <code>CxfRsProducer</code> will use the <code>HttpClientAPI</code> to invoke the service. If it is false, the <code>CxfRsProducer</code> will use the <code>ProxyClientAPI</code> to invoke the service.	<code>true</code>	<code>boolean</code>
ignoreDeleteMethodMessageBody (producer (advanced))	This option is used to tell <code>CxfRsProducer</code> to ignore the message body of the DELETE method when using HTTP API.	<code>false</code>	<code>boolean</code>

Name	Description	Default	Type
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
maxClientCacheSize (producer (advanced))	This option allows you to configure the maximum size of the cache. The implementation caches CXF clients or ClientFactoryBean in CxfProvider and CxfRsProvider.	10	int
synchronous (producer (advanced))	Sets whether synchronous processing should be strictly used.	false	boolean
binding (advanced)	To use a custom CxfBinding to control the binding between Camel Message and CXF Message.		CxfRsBinding
bus (advanced)	To use a custom configured CXF Bus.		Bus
continuationTimeout (advanced)	This option is used to set the CXF continuation timeout which could be used in CxfConsumer by default when the CXF server is using Jetty or Servlet transport.	30000	long
cxfRsConfigurer (advanced)	This option could apply the implementation of org.apache.camel.component.cxf.jaxrs.CxfRsEndpointConfigurer which supports to configure the CXF endpoint in programmatic way. User can configure the CXF server and client by implementing configure\\{Server/Client} method of CxfEndpointConfigurer.		CxfRsConfigurer
defaultBus (advanced)	Will set the default bus when CXF endpoint create a bus by itself.	false	boolean
headerFilterStrategy (advanced)	To use a custom HeaderFilterStrategy to filter header to and from Camel message.		HeaderFilterStrategy

Name	Description	Default	Type
performInvocation (advanced)	When the option is true, Camel will perform the invocation of the resource class instance and put the response object into the exchange for further processing.	false	boolean
propagateContexts (advanced)	When the option is true, JAXRS UriInfo, HttpHeaders, Request and SecurityContext contexts will be available to custom CXFRS processors as typed Camel exchange properties. These contexts can be used to analyze the current requests using JAX-RS API.	false	boolean

30.6. MESSAGE HEADERS

The CXF-RS component supports 16 message header(s), which is/are listed below:

Name	Description	Default	Type
operationName (common) Constant: OPERATION_NAME	The name of the operation.		String
CamelAuthentication (common) Constant: AUTHENTICATION	The authentication.		Subject
CamelHttpMethod (common) Constant: HTTP_METHOD	The http method to use.		String
CamelHttpPath (common) Constant: HTTP_PATH	The http path.		String

Name	Description	Default	Type
Content-Type (common) Constant: CONTENT_TYPE	The content type.		String
CamelHttpQuery (common) Constant: HTTP_QUERY	The http query.		String
CamelHttpResponseCode (common) Constant: HTTP_RESPONSE_CODE	The http response code.		Integer
Content-Encoding (common) Constant: CONTENT_ENCODING	The content encoding.		String
org.apache.cxf.message.Message. PROTOCOL_HEADERS (common) Constant: PROTOCOL_HEADERS	The protocol headers.		Map
CamelCxfMessage (common) Constant: CAMEL_CXF_MESSAGE	The CXF message.		Message

Name	Description	Default	Type
CamelCxfRsUsingHttpAPI (common) Constant: CAMEL_CXF_RS_USING_HTTP_API	If it is true, the CxfRsProducer will use the HttpClientAPI to invoke the service. If it is false, the CxfRsProducer will use the ProxyClientAPI to invoke the service.		Boolean
CamelCxfRsVarValues (common) Constant: CAMEL_CXF_RS_VAR_VALUES	The path values.		Object[]
CamelCxfRsResponseClass (common) Constant: CAMEL_CXF_RS_RESPONSE_CLASSES	The response class.		Class
CamelCxfRsResponseGenericType (common) Constant: CAMEL_CXF_RS_RESPONSE_GENERIC_TYPE	The response generic type.		Type
CamelCxfRsQueryMap (common) Constant: CAMEL_CXF_RS_QUERY_MAP	The query map.		Map
CamelCxfRsOperationResourceInfoStack (common) Constant: CAMEL_CXF_RS_OPERATION_RESOURCE_INFO_STACK	The stack of MethodInvocationInfo representing resources path when JAX-RS invocation looks for target.		OperationResourceInfoStack

You can also configure the CXF REST endpoint through the spring configuration.

NOTE

Avoid creating your own HTTP server instances in a Camel Spring Boot application by using either of the **`cxf-rt-transport-jetty`**, **`cxf-rt-transport-netty-server`**, **`cxf-rt-transport-undertow`** libraries. It is recommended to use the Spring Boot embedded HTTP server stack which is created when you use the **`spring-boot-starter-web`**, **`cxf-spring-boot-starter-jaxrs`**, or **`cxf-spring-boot-starter-jaxws`** dependencies.

NOTE

Since there are lots of differences between the CXF REST client and CXF REST Server, we provide different configuration for them.

+ Please check the following files for more details:

- the [schema file](#).
- [CXF JAX-RS documentation](#).

30.7. HOW TO CONFIGURE THE REST ENDPOINT IN CAMEL

In the [camel-cxf schema file](#), there are two elements for the REST endpoint definition:

- **`cxf:rsServer`** for REST consumer
- **`cxf:rsClient`** for REST producer.

You can find a Camel REST service route configuration example there.

30.8. HOW TO OVERRIDE THE CXF PRODUCER ADDRESS FROM MESSAGE HEADER

The **`camel-cxf:rs`** producer supports overriding the service address by setting the message with the key of **`CamelDestinationOverrideUrl`**.

```
// set up the service address from the message header to override the setting of CXF endpoint
exchange.getIn().setHeader(Exchange.DESTINATION_OVERRIDE_URL,
constant(getServiceAddress()));
```

30.9. CONSUMING A REST REQUEST - SIMPLE BINDING STYLE

Since Camel 2.11

The **Default** binding style is rather low-level, requiring the user to manually process the **`MessageContentsList`** object coming into the route. Thus, it tightly couples the route logic with the method signature and parameter indices of the JAX-RS operation which is somewhat inelegant, difficult and error-prone.

In contrast, the **`SimpleConsumer`** binding style performs the following mappings, to **make the request data more accessible** to you within the Camel Message:

- JAX-RS Parameters (**@HeaderParam**, **@QueryParam**, etc.) are injected as *IN* message headers. The header name matches the value of the annotation.
- The request entity (POJO or another type) becomes the *IN* message body. If a single entity cannot be identified in the JAX-RS method signature, it falls back to the original **MessageContentsList**.
- Binary **@Multipart** body parts become *IN* message attachments, supporting **DataHandler**, **InputStream**, **DataSource** and CXF's **Attachment** class.
- Non-binary **@Multipart** body parts are mapped as *IN* message headers. The header name matches the Body Part name.

Additionally, the following rules apply to the **Response** mapping:

- If the message body type is different to **javax.ws.rs.core.Response** (user-built response), a new **Response** is created and the message body is set as the entity (so long it's not null). The response status code is taken from the **Exchange.HTTP_RESPONSE_CODE** header, or defaults to 200 OK if not present.
- If the message body type is equal to **javax.ws.rs.core.Response**, it means that the user has built a custom response, and therefore it is respected, and it becomes the final response.
- In all cases, Camel headers permitted by custom or default **HeaderFilterStrategy** are added to the HTTP response.

30.9.1. Enabling the Simple Binding Style

This binding style can be activated by setting the **bindingStyle** parameter in the consumer endpoint to value **SimpleConsumer**:

```
from("cxfrs:bean:rsServer?bindingStyle=SimpleConsumer")
  .to("log:TEST?showAll=true");
```

30.9.2. Examples of request binding with different method signatures

Below is a list of method signatures along with the expected result from the simple binding:

- **public Response doAction(BusinessObject request);** the request payload is placed in the *IN* message body, replacing the original **MessageContentsList**.
- **public Response doAction(BusinessObject request, @HeaderParam("abcd") String abcd, @QueryParam("defg") String defg);** the request payload is placed in the *IN* message body, replacing the original **MessageContentsList**. Both request parameters are mapped as *IN* message headers with names "abcd" and "defg".
- **public Response doAction(@HeaderParam("abcd") String abcd, @QueryParam("defg") String defg);** both request parameters are mapped as the *IN* message headers with names "abcd" and "defg". The original **MessageContentsList** is preserved, even though it only contains the two parameters.
- **public Response doAction(@Multipart(value="body1") BusinessObject request, @Multipart(value="body2") BusinessObject request2);** the first parameter is transferred as a header with name "body1", and the second one is mapped as header "body2". The original

MessageContentsList is preserved as the *IN* message body.

- **public Response doAction(InputStream abcd);** the **InputStream** is unwrapped from the **MessageContentsList** and preserved as the *IN* message body.
- **public Response doAction(DataHandler abcd);** the *DataHandler* is unwrapped from the **MessageContentsList** and preserved as the *IN* message body.

30.9.3. Examples of the Simple Binding Style

Given a JAX-RS resource class with this method:

```
@POST @Path("/customers/{type}")
public Response newCustomer(Customer customer, @PathParam("type") String type,
    @QueryParam("active") @DefaultValue("true") boolean active) {
    return null;
}
```

Serviced by the following route:

```
from("cxfrs:bean:rsServer?bindingStyle=SimpleConsumer")
    .recipientList(simple("direct:${header.operationName}"));

from("direct:newCustomer")
    .log("Request: type=${header.type}, active=${header.active}, customerData=${body}");
```

The following HTTP request with XML payload (given that the Customer DTO is JAXB-annotated):

```
POST /customers/gold?active=true

Payload:
<Customer>
  <fullName>Raul Kripalani</fullName>
  <country>Spain</country>
  <project>Apache Camel</project>
</Customer>
```

Will print the message:

```
Request: type=gold, active=true, customerData=<Customer.toString() representation>
```

NOTE

More examples on how to process requests and write responses can be found [here](#).

30.10. CONSUMING A REST REQUEST - DEFAULT BINDING STYLE

The [CXF JAXRS front end](#) implements the [JAX-RS \(JSR-311\) API](#), so we can export the resource classes as a REST service. We leverage the [CXF Invoker API](#) to turn a REST request into a normal Java object method invocation. There is no need to specify the URI template within your endpoint. The CXF takes care of the REST request URI to resource class method mapping according to the JSR-311 specification. All you need to do in Camel is delegate this method request to the right processor or endpoint.

CXF-RS route example

```
private static final String CXF_RS_ENDPOINT_URI =
    "cxfrs://http://localhost:" + CXT + "/rest?";
resourceClasses=org.apache.camel.component.cxf.jaxrs.testbean.CustomerServiceResource";
private static final String CXF_RS_ENDPOINT_URI2 =
    "cxfrs://http://localhost:" + CXT + "/rest2?";
resourceClasses=org.apache.camel.component.cxf.jaxrs.testbean.CustomerService";
private static final String CXF_RS_ENDPOINT_URI3 =
    "cxfrs://http://localhost:" + CXT + "/rest3?";
+
"resourceClasses=org.apache.camel.component.cxf.jaxrs.testbean.CustomerServiceNoAnnotations&"

    + "modelRef=classpath:/org/apache/camel/component/cxf/jaxrs/CustomerServiceModel.xml";
private static final String CXF_RS_ENDPOINT_URI4 =
    "cxfrs://http://localhost:" + CXT + "/rest4?";
+
"modelRef=classpath:/org/apache/camel/component/cxf/jaxrs/CustomerServiceDefaultHandlerModel.xml";
private static final String CXF_RS_ENDPOINT_URI5 =
    "cxfrs://http://localhost:" + CXT + "/rest5?";
    + "propagateContexts=true&"
    +
"modelRef=classpath:/org/apache/camel/component/cxf/jaxrs/CustomerServiceDefaultHandlerModel.xml";
protected RouteBuilder createRouteBuilder() throws Exception {
    final Processor testProcessor = new TestProcessor();
    final Processor testProcessor2 = new TestProcessor2();
    final Processor testProcessor3 = new TestProcessor3();
    return new RouteBuilder() {
        public void configure() {
            errorHandler(new NoErrorHandlerBuilder());
            from(CXF_RS_ENDPOINT_URI).process(testProcessor);
            from(CXF_RS_ENDPOINT_URI2).process(testProcessor);
            from(CXF_RS_ENDPOINT_URI3).process(testProcessor);
            from(CXF_RS_ENDPOINT_URI4).process(testProcessor2);
            from(CXF_RS_ENDPOINT_URI5).process(testProcessor3);
        }
    };
}
```

And the corresponding resource class is used to configure the endpoint.

NOTE

By default, JAX-RS resource classes are **only** used to configure JAX-RS properties. Methods will **not** be executed during routing of messages to the endpoint. Instead, it is the responsibility of the route to do all processing.

It is sufficient to provide an interface only as opposed to a no-op service implementation class for the default mode.

If a **performInvocation** option is enabled, the service implementation will be invoked first, the response will be set on the Camel exchange, and the route execution will continue as usual. This can be useful for integrating the existing JAX-RS implementations into Camel routes and for post-processing JAX-RS Responses in custom processors.

```

@Path("/customerservice/")
public interface CustomerServiceResource {

    @GET
    @Path("/customers/{id}/")
    Customer getCustomer(@PathParam("id") String id);

    @PUT
    @Path("/customers/")
    Response updateCustomer(Customer customer);

    @Path("/{id}")
    @PUT()
    @Consumes({ "application/xml", "text/plain",
                "application/json" })
    @Produces({ "application/xml", "text/plain",
                "application/json" })
    Object invoke(@PathParam("id") String id,
                  String payload);
}

```

30.11. HOW TO INVOKE THE REST SERVICE THROUGH CAMEL-CXFRS PRODUCER

The [CXF JAXRS front end](#) implements a [proxy-based client API](#). With this API you can invoke the remote REST service through a proxy. The **camel-cxfrs** producer is based on this [proxy API](#). You can specify the operation name in the message header and prepare the parameter in the message body, the camel-cxfrs producer will generate the right REST request for you.

Example

```

Exchange exchange = template.send("direct://proxy", new Processor() {
    public void process(Exchange exchange) throws Exception {
        exchange.setPattern(ExchangePattern.InOut);
        Message inMessage = exchange.getIn();
        // set the operation name
        inMessage.setHeader(CxfConstants.OPERATION_NAME, "getCustomer");
        // using the proxy client API
        inMessage.setHeader(CxfConstants.CAMEL_CXF_RS_USING_HTTP_API, Boolean.FALSE);
        // set a customer header
        inMessage.setHeader("key", "value");
        // set up the accepted content type
        inMessage.setHeader(Exchange.ACCEPT_CONTENT_TYPE, "application/json");
        // set the parameters, if you just have one parameter,
        // camel will put this object into an Object[] itself
        inMessage.setBody("123");
    }
});

// get the response message
Customer response = (Customer) exchange.getMessage().getBody();

assertNotNull(response, "The response should not be null");
assertEquals(123, response.getId(), "Get a wrong customer id");

```

```

assertEquals("John", response.getName(), "Get a wrong customer name");
assertEquals(200, exchange.getMessage().getHeader(Exchange.HTTP_RESPONSE_CODE), "Get
a wrong response code");
assertEquals("value", exchange.getMessage().getHeader("key"), "Get a wrong header value");

```

The [CXF JAXRS front end](#) also provides an [HTTP centric client API](#). You can also invoke this API from camel-cxf-rs producer. You need to specify the [HTTP_PATH](#) and the [HTTP_METHOD](#) and let the producer use the http centric client API by using the URI option `httpClientAPI` or by setting the message header [CxfConstants.CAMEL_CXF_RS_USING_HTTP_API](#). You can turn the response object to the type class specified with the message header [CxfConstants.CAMEL_CXF_RS_RESPONSE_CLASS](#).

```

Exchange exchange = template.send("direct://http", new Processor() {
    public void process(Exchange exchange) throws Exception {
        exchange.setPattern(ExchangePattern.InOut)
        Message inMessage = exchange.getIn();
        // using the http central client API
        inMessage.setHeader(CxfConstants.CAMEL_CXF_RS_USING_HTTP_API, Boolean.TRUE);
        // set the Http method
        inMessage.setHeader(Exchange.HTTP_METHOD, "GET");
        // set the relative path
        inMessage.setHeader(Exchange.HTTP_PATH, "/customerservice/customers/123");
        // Specify the response class, cxfrs will use InputStream as the response object type
        inMessage.setHeader(CxfConstants.CAMEL_CXF_RS_RESPONSE_CLASS, Customer.class);
        // set a customer header
        inMessage.setHeader("key", "value");
        // since we use the Get method, so we don't need to set the message body
        inMessage.setBody(null);
    }
});

```

You can also specify the query parameters from cxfrs URI for the CXFRS http centric client.

```

Exchange exchange = template.send("cxfrs://http://localhost:9003/testQuery?
httpClientAPI=true&q1=12&q2=13"

```

To support the Dynamical routing, you can override the URI's query parameters by using the [CxfConstants.CAMEL_CXF_RS_QUERY_MAP](#) header to set the parameter map for it.

```

Map<String, String> queryMap = new LinkedHashMap<>();
queryMap.put("q1", "new");
queryMap.put("q2", "world");
inMessage.setHeader(CxfConstants.CAMEL_CXF_RS_QUERY_MAP, queryMap);

```

30.12. SPRING BOOT AUTO-CONFIGURATION

The component supports 6 options, which are listed below.

Name	Description	Default	Type
camel.component. cxfrs.autowired- enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component. cxfrs.bridge- error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions (if possible) occurred while the Camel consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. Important: This is only possible if the 3rd party component allows Camel to be alerted if an exception was thrown. Some components handle this internally only, and therefore bridgeErrorHandler is not possible. In other situations we may improve the Camel component to hook into the 3rd party component and make this possible for future releases. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component. cxfrs.enabled	Whether to enable auto configuration of the cxfrs component. This is enabled by default.		Boolean
camel.component. cxfrs.header- filter-strategy	To use a custom org.apache.camel.spi.HeaderFilterStrategy to filter header to and from Camel message. The option is a org.apache.camel.spi.HeaderFilterStrategy type.		HeaderFilterStrategy
camel.component. cxfrs.lazy-start- producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component. cxfrs.use-global- ssl-context- parameters	Enable usage of global SSL context parameters.	false	Boolean

CHAPTER 31. DATA FORMAT

Only producer is supported

The Dataformat component allows to use the [Data Format](#) as a Camel Component.

31.1. DEPENDENCIES

When using **dataformat** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-dataformat-starter</artifactId>
</dependency>
```

31.2. URI FORMAT

```
dataformat:name:(marshal|unmarshal)[?options]
```

Where **name** is the name of the Data Format. And then followed by the operation which must either be **marshal** or **unmarshal**. The options is used for configuring the [Data Format](#) in use. See the Data Format documentation for which options it support.

31.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

31.3.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).
- directly in the Java code.

31.3.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

31.4. COMPONENT OPTIONS

The Data Format component supports 2 options, which are listed below.

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

31.5. ENDPOINT OPTIONS

The Data Format endpoint is configured using URI syntax:

```
dataformat:name:operation
```

with the following path and query parameters:

31.5.1. Path Parameters (2 parameters)

Name	Description	Default	Type
name (producer)	Required Name of data format.		String
operation (producer)	Required Operation to use either marshal or unmarshal. Enum values: • marshal • unmarshal		String

31.5.2. Query Parameters (1 parameters)

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

31.6. SAMPLES

For example to use the [JAXB Data Format](#) we can do as follows:

```
from("activemq:My.Queue").
  to("dataformat:jaxb:unmarshal?contextPath=com.acme.model").
  to("mqseries:Another.Queue");
```

And in XML DSL you do:

```
<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="activemq:My.Queue"/>
    <to uri="dataformat:jaxb:unmarshal?contextPath=com.acme.model"/>
  </route>
</camelContext>
```

```

    <to uri="mqseries:Another.Queue"/>
  </route>
</camelContext>

```

31.7. SPRING BOOT AUTO-CONFIGURATION

The component supports 3 options, which are listed below.

Name	Description	Default	Type
camel.component.dataformat.auto-wired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.dataformat.enabled	Whether to enable auto configuration of the dataformat component. This is enabled by default.		Boolean
camel.component.dataformat.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 32. DATASET

Both producer and consumer are supported

Testing of distributed and asynchronous processing is notoriously difficult. The [Mock](#), [Test](#) and [DataSet](#) endpoints work great with the Camel Testing Framework to simplify your unit and integration testing using [Enterprise Integration Patterns](#) and Camel's large range of Components together with the powerful Bean Integration.

The DataSet component provides a mechanism to easily perform load & soak testing of your system. It works by allowing you to create [DataSet instances](#) both as a source of messages and as a way to assert that the data set is received.

Camel will use the [throughput logger](#) when sending datasets.

32.1. DEPENDENCIES

When using **dataset** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-dataset-starter</artifactId>
</dependency>
```

32.2. URI FORMAT

```
dataset:name[?options]
```

Where **name** is used to find the [DataSet instance](#) in the Registry

Camel ships with a support implementation of **org.apache.camel.component.dataset.DataSet**, the **org.apache.camel.component.dataset.DataSetSupport** class, that can be used as a base for implementing your own DataSet. Camel also ships with some implementations that can be used for testing: **org.apache.camel.component.dataset.SimpleDataSet**, **org.apache.camel.component.dataset.ListDataSet** and **org.apache.camel.component.dataset.FileDataSet**, all of which extend **DataSetSupport**.

32.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

32.3.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a

few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).
- directly in the Java code.

32.3.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

32.4. COMPONENT OPTIONS

The Dataset component supports 5 options, which are listed below.

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
log (producer)	To turn on logging when the mock receives an incoming message. This will log only one time at INFO level for the incoming message. For more detailed logging then set the logger to DEBUG level for the org.apache.camel.component.mock.MockEndpoint class.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
exchangeFormatter (advanced)	Autowired Sets a custom ExchangeFormatter to convert the Exchange to a String suitable for logging. If not specified, we default to DefaultExchangeFormatter.		ExchangeFormatter

32.5. ENDPOINT OPTIONS

The Dataset endpoint is configured using URI syntax:

```
dataset:name
```

with the following path and query parameters:

32.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
name (common)	Required Name of DataSet to lookup in the registry.		DataSet

32.5.2. Query Parameters (21 parameters)

Name	Description	Default	Type
dataSetIndex (common)	Controls the behaviour of the CamelDataSetIndex header. For Consumers: - off = the header will not be set - strict/lenient = the header will be set For Producers: - off = the header value will not be verified, and will not be set if it is not present = strict = the header value must be present and will be verified = lenient = the header value will be verified if it is present, and will be set if it is not present. Enum values: • strict • lenient • off	lenient	String
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
initialDelay (consumer)	Time period in millis to wait before starting sending messages.	1000	long
minRate (consumer)	Wait until the DataSet contains at least this number of messages.	0	int
preloadSize (consumer)	Sets how many messages should be preloaded (sent) before the route completes its initialization.	0	long
produceDelay (consumer)	Allows a delay to be specified which causes a delay when a message is sent by the consumer (to simulate slow processing).	3	long
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler

Name	Description	Default	Type
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: ● InOnly ● InOut ● InOptionalOut		ExchangePattern
assertPeriod (producer)	Sets a grace period after which the mock endpoint will re-assert to ensure the preliminary assertion is still valid. This is used for example to assert that exactly a number of messages arrives. For example if <code>expectedMessageCount(int)</code> was set to 5, then the assertion is satisfied when 5 or more message arrives. To ensure that exactly 5 messages arrives, then you would need to wait a little period to ensure no further message arrives. This is what you can use this method for. By default this period is disabled.		long
consumeDelay (producer)	Allows a delay to be specified which causes a delay when a message is consumed by the producer (to simulate slow processing).	0	long
expectedCount (producer)	Specifies the expected number of message exchanges that should be received by this endpoint. Beware: If you want to expect that 0 messages, then take extra care, as 0 matches when the tests starts, so you need to set a assert period time to let the test run for a while to make sure there are still no messages arrived; for that use <code>setAssertPeriod(long)</code>. An alternative is to use <code>NotifyBuilder</code>, and use the notifier to know when Camel is done routing some messages, before you call the <code>assertIsSatisfied()</code> method on the mocks. This allows you to not use a fixed assert period, to speedup testing times. If you want to assert that exactly n'th message arrives to this mock endpoint, then see also the <code>setAssertPeriod(long)</code> method for further details.	-1	int
failFast (producer)	Sets whether <code>assertIsSatisfied()</code> should fail fast at the first detected failed expectation while it may otherwise wait for all expected messages to arrive before performing expectations verifications. Is by default true. Set to false to use behavior as in Camel 2.x.	false	boolean

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
log (producer)	To turn on logging when the mock receives an incoming message. This will log only one time at INFO level for the incoming message. For more detailed logging then set the logger to DEBUG level for the org.apache.camel.component.mock.MockEndpoint class.	false	boolean
reportGroup (producer)	A number that is used to turn on throughput logging based on groups of the size.		int
resultMinimumWaitTime (producer)	Sets the minimum expected amount of time (in millis) the assertIsSatisfied() will wait on a latch until it is satisfied.		long
resultWaitTime (producer)	Sets the maximum amount of time (in millis) the assertIsSatisfied() will wait on a latch until it is satisfied.		long
retainFirst (producer)	Specifies to only retain the first n'th number of received Exchanges. This is used when testing with big data, to reduce memory consumption by not storing copies of every Exchange this mock endpoint receives. Important: When using this limitation, then the getReceivedCounter() will still return the actual number of received Exchanges. For example if we have received 5000 Exchanges, and have configured to only retain the first 10 Exchanges, then the getReceivedCounter() will still return 5000 but there is only the first 10 Exchanges in the getExchanges() and getReceivedExchanges() methods. When using this method, then some of the other expectation methods is not supported, for example the expectedBodiesReceived(Object...) sets a expectation on the first number of bodies received. You can configure both setRetainFirst(int) and setRetainLast(int) methods, to limit both the first and last received.	-1	int

Name	Description	Default	Type
retainLast (producer)	Specifies to only retain the last n'th number of received Exchanges. This is used when testing with big data, to reduce memory consumption by not storing copies of every Exchange this mock endpoint receives. Important: When using this limitation, then the <code>getReceivedCounter()</code> will still return the actual number of received Exchanges. For example if we have received 5000 Exchanges, and have configured to only retain the last 20 Exchanges, then the <code>getReceivedCounter()</code> will still return 5000 but there is only the last 20 Exchanges in the <code>getExchanges()</code> and <code>getReceivedExchanges()</code> methods. When using this method, then some of the other expectation methods is not supported, for example the <code>expectedBodiesReceived(Object...)</code> sets a expectation on the first number of bodies received. You can configure both <code>setRetainFirst(int)</code> and <code>setRetainLast(int)</code> methods, to limit both the first and last received.	-1	int
sleepForEmptyTest (producer)	Allows a sleep to be specified to wait to check that this endpoint really is empty when <code>expectedMessageCount(int)</code> is called with zero.		long
copyOnExchange (producer (advanced))	Sets whether to make a deep copy of the incoming Exchange when received at this mock endpoint. Is by default true.	true	boolean

32.6. CONFIGURING DATASET

Camel will lookup in the Registry for a bean implementing the `DataSet` interface. So you can register your own `DataSet` as:

```
<bean id="myDataSet" class="com.mycompany.MyDataSet">
  <property name="size" value="100"/>
</bean>
```

32.7. EXAMPLE

For example, to test that a set of messages are sent to a queue and then consumed from the queue without losing any messages:

```
// send the dataset to a queue
from("dataset:foo").to("activemq:SomeQueue");

// now lets test that the messages are consumed correctly
from("activemq:SomeQueue").to("dataset:foo");
```

The above would look in the Registry to find the **foo** DataSet instance which is used to create the messages.

Then you create a DataSet implementation, such as using the **SimpleDataSet** as described below, configuring things like how big the data set is and what the messages look like etc.

32.8. DATASETSUPPORT (ABSTRACT CLASS)

The DataSetSupport abstract class is a nice starting point for new DataSets, and provides some useful features to derived classes.

32.8.1. Properties on DataSetSupport

Property	Type	Default	Description
defaultHeaders	Map<String, Object>	null	Specifies the default message body. For SimpleDataSet it is a constant payload; though if you want to create custom payloads per message, create your own derivation of DataSetSupport .
outputTransformer	org.apache.camel.Processor	null	
size	long	10	Specifies how many messages to send/consume.
reportCount	long	-1	Specifies the number of messages to be received before reporting progress. Useful for showing progress of a large load test. If < 0, then size / 5, if is 0 then size , else set to reportCount value.

32.9. SIMPLEDATASET

The **SimpleDataSet** extends **DataSetSupport**, and adds a default body.

32.9.1. Additional Properties on SimpleDataSet

Property	Type	Default	Description
----------	------	---------	-------------

Property	Type	Default	Description
defaultBody	Object	<hello>world! </hello>	Specifies the default message body. By default, the SimpleDataSet produces the same constant payload for each exchange. If you want to customize the payload for each exchange, create a Camel Processor and configure the SimpleDataSet to use it by setting the outputTransformer property.

32.10. LISTDATASET

The `ListDataSet` extends **DataSetSupport**, and adds a list of default bodies.

32.10.1. Additional Properties on ListDataSet

Property	Type	Default	Description
defaultBodies	List<Object>	empty LinkedList<Object>	Specifies the default message body. By default, the ListDataSet selects a constant payload from the list of defaultBodies using the CamelDataSetIndex . If you want to customize the payload, create a Camel Processor and configure the ListDataSet to use it by setting the outputTransformer property.
size	long	the size of the defaultBodies list	Specifies how many messages to send/consume. This value can be different from the size of the defaultBodies list. If the value is less than the size of the defaultBodies list, some of the list elements will not be used. If the value is greater than the size of the defaultBodies list, the payload for the exchange will be selected using the modulus of the CamelDataSetIndex and the size of the defaultBodies list (i.e. CamelDataSetIndex % defaultBodies.size())

32.11. FILEDATASET

The **FileDataSet** extends **ListDataSet**, and adds support for loading the bodies from a file.

32.11.1. Additional Properties on FileDataSet

Property	Type	Default	Description
sourceFile	File	null	Specifies the source file for payloads
delimiter	String	\z	Specifies the delimiter pattern used by a java.util.Scanner to split the file into multiple payloads.

32.12. SPRING BOOT AUTO-CONFIGURATION

The component supports 11 options, which are listed below.

Name	Description	Default	Type
camel.component.dataset-test.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.dataset-test.enabled	Whether to enable auto configuration of the dataset-test component. This is enabled by default.		Boolean
camel.component.dataset-test.exchange-formatter	Sets a custom ExchangeFormatter to convert the Exchange to a String suitable for logging. If not specified, we default to DefaultExchangeFormatter. The option is a <code>org.apache.camel.spi.ExchangeFormatter</code> type.		ExchangeFormatter
camel.component.dataset-test.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.dataset-test.log	To turn on logging when the mock receives an incoming message. This will log only one time at INFO level for the incoming message. For more detailed logging then set the logger to DEBUG level for the <code>org.apache.camel.component.mock.MockEndpoint</code> class.	false	Boolean
camel.component.dataset.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.dataset.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.dataset.enabled	Whether to enable auto configuration of the dataset component. This is enabled by default.		Boolean
camel.component.dataset.exchange-formatter	Sets a custom <code>ExchangeFormatter</code> to convert the Exchange to a String suitable for logging. If not specified, we default to <code>DefaultExchangeFormatter</code> . The option is a <code>org.apache.camel.spi.ExchangeFormatter</code> type.		<code>ExchangeFormatter</code>
camel.component.dataset.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow <code>CamelContext</code> and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.dataset.log	To turn on logging when the mock receives an incoming message. This will log only one time at INFO level for the incoming message. For more detailed logging then set the logger to DEBUG level for the <code>org.apache.camel.component.mock.MockEndpoint</code> class.	false	Boolean

CHAPTER 33. DIRECT

Both producer and consumer are supported

The Direct component provides direct, synchronous invocation of any consumers when a producer sends a message exchange.

This endpoint can be used to connect existing routes in the **same** camel context.

NOTE

Asynchronous

The [SEDA](#) component provides asynchronous invocation of any consumers when a producer sends a message exchange.

33.1. DEPENDENCIES

When using **direct** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-direct-starter</artifactId>
</dependency>
```

33.2. URI FORMAT

```
direct:someName[?options]
```

Where **someName** can be any string to uniquely identify the endpoint

33.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

33.3.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).

- directly in the Java code.

33.3.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

33.4. COMPONENT OPTIONS

The Direct component supports 5 options, which are listed below.

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
block (producer)	If sending a message to a direct endpoint which has no active consumer, then we can tell the producer to block and wait for the consumer to become active.	true	boolean

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
timeout (producer)	The timeout value to use if block is enabled.	30000	long
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

33.5. ENDPOINT OPTIONS

The Direct endpoint is configured using URI syntax:

```
direct:name
```

with the following path and query parameters:

33.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
name (common)	Required Name of direct endpoint.		String

33.5.2. Query Parameters (8 parameters)

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer (advanced))	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		<code>ExceptionHandler</code>
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • <code>InOnly</code> • <code>InOut</code> • <code>InOptionalOut</code>		<code>ExchangePattern</code>
block (producer)	If sending a message to a direct endpoint which has no active consumer, then we can tell the producer to block and wait for the consumer to become active.	true	boolean
failIfNoConsumers (producer)	Whether the producer should fail by throwing an exception, when sending to a <code>DIRECT</code> endpoint with no active consumers.	true	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow <code>CamelContext</code> and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

Name	Description	Default	Type
timeout (producer)	The timeout value to use if block is enabled.	30000	long
synchronous (advanced)	Whether synchronous processing is forced. If enabled then the producer thread, will be forced to wait until the message has been completed before the same thread will continue processing. If disabled (default) then the producer thread may be freed and can do other work while the message is continued processed by other threads (reactive).	false	boolean

33.6. SAMPLES

In the route below we use the direct component to link the two routes together:

```
from("activemq:queue:order.in")
  .to("bean:orderServer?method=validate")
  .to("direct:processOrder");

from("direct:processOrder")
  .to("bean:orderService?method=process")
  .to("activemq:queue:order.out");
```

And the sample using spring DSL:

```
<route>
  <from uri="activemq:queue:order.in"/>
  <to uri="bean:orderService?method=validate"/>
  <to uri="direct:processOrder"/>
</route>

<route>
  <from uri="direct:processOrder"/>
  <to uri="bean:orderService?method=process"/>
  <to uri="activemq:queue:order.out"/>
</route>
```

See also samples from the [SEDA](#) component, how they can be used together.

33.7. SPRING BOOT AUTO-CONFIGURATION

The component supports 6 options, which are listed below.

Name	Description	Default	Type
camel.component. .direct.autowired- enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component. .direct.block	If sending a message to a direct endpoint which has no active consumer, then we can tell the producer to block and wait for the consumer to become active.	true	Boolean
camel.component. .direct.bridge- error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component. .direct.enabled	Whether to enable auto configuration of the direct component. This is enabled by default.		Boolean
camel.component. .direct.lazy-start- producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component. .direct.timeout	The timeout value to use if block is enabled.	30000	Long

CHAPTER 34. ELASTICSEARCH

Since Camel 3.18.3

Only producer is supported

The ElasticSearch component allows you to interface with an [ElasticSearch](#) 8.x API using the Java API Client library.

34.1. DEPENDENCIES

When using **elasticsearch** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-elasticsearch-starter</artifactId>
</dependency>
```

34.2. URI FORMAT

```
elasticsearch://clusterName[?options]
```

34.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

34.3.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).
- directly in the Java code.

34.3.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

34.4. COMPONENT OPTIONS

The Elasticsearch component supports 14 options, which are listed below.

Name	Description	Default	Type
connectionTimeout (producer)	The time in ms to wait before connection will timeout.	30000	int
hostAddresses (producer)	Comma separated list with ip:port formatted remote transport addresses to use. The ip and port options must be left blank for hostAddresses to be considered instead.		String
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
maxRetryTimeout (producer)	The time in ms before retry.	30000	int
socketTimeout (producer)	The timeout in ms to wait before the socket will timeout.	30000	int

Name	Description	Default	Type
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
client (advanced)	Autowired To use an existing configured Elasticsearch client, instead of creating a client per endpoint. This allow to customize the client with specific settings.		RestClient
enableSniffer (advanced)	Enable automatically discover nodes from a running Elasticsearch cluster. If this option is used in conjunction with Spring Boot then it's managed by the Spring Boot configuration (see: Disable Sniffer in Spring Boot).	false	boolean
sniffAfterFailure Delay (advanced)	The delay of a sniff execution scheduled after a failure (in milliseconds).	60000	int
snifferInterval (advanced)	The interval between consecutive ordinary sniff executions in milliseconds. Will be honoured when sniffOnFailure is disabled or when there are no failures between consecutive sniff executions.	30000 0	int
certificatePath (security)	The path of the self-signed certificate to use to access to Elasticsearch.		String
enableSSL (security)	Enable SSL.	false	boolean
password (security)	Password for authenticate.		String
user (security)	Basic authenticate user.		String

34.5. ENDPOINT OPTIONS

The Elasticsearch endpoint is configured using URI syntax:

```
elasticsearch:clusterName
```

with the following path and query parameters:

34.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
clusterName (producer)	Required Name of the cluster.		String

34.5.2. Query Parameters (19 parameters)

Name	Description	Default	Type
connectionTimeout (producer)	The time in ms to wait before connection will timeout.	30000	int
disconnect (producer)	Disconnect after it finish calling the producer.	false	boolean
from (producer)	Starting index of the response.		Integer
hostAddresses (producer)	Comma separated list with ip:port formatted remote transport addresses to use.		String
indexName (producer)	The name of the index to act against.		String
maxRetryTimeout (producer)	The time in ms before retry.	30000	int

Name	Description	Default	Type
operation (producer)	What operation to perform. Enum values: • Index • Update • Bulk • GetById • MultiGet • MultiSearch • Delete • DeleteIndex • Search • Exists • Ping		ElasticsearchOperation
scrollKeepAliveMs (producer)	Time in ms during which elasticsearch will keep search context alive.	60000	int
size (producer)	Size of the response.		Integer
socketTimeout (producer)	The timeout in ms to wait before the socket will timeout.	30000	int
useScroll (producer)	Enable scroll usage.	false	boolean
waitForActiveShards (producer)	Index creation waits for the write consistency number of shards to be available.	1	int
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

Name	Description	Default	Type
documentClass (advanced)	The class to use when deserializing the documents.	Object Node	Class
enableSniffer (advanced)	Enable automatically discover nodes from a running Elasticsearch cluster. If this option is used in conjunction with Spring Boot then it's managed by the Spring Boot configuration (see: Disable Sniffer in Spring Boot).	false	boolean
sniffAfterFailure Delay (advanced)	The delay of a sniff execution scheduled after a failure (in milliseconds).	60000	int
snifferInterval (advanced)	The interval between consecutive ordinary sniff executions in milliseconds. Will be honoured when sniffOnFailure is disabled or when there are no failures between consecutive sniff executions.	30000 0	int
certificatePath (security)	The path of the self-signed certificate to use to access to Elasticsearch.		String
enableSSL (security)	Enable SSL.	false	boolean

34.6. MESSAGE HEADERS

The Elasticsearch component supports 9 message header(s), which is/are listed below:

Name	Description	Default	Type
------	-------------	---------	------

Name	Description	Default	Type
operation (producer) Constant: PARAM_OPERATION	The operation to perform. Enum values: • Index • Update • Bulk • GetById • MultiGet • MultiSearch • Delete • DeleteIndex • Search • Exists • Ping		ElasticsearchOperation
indexId (producer) Constant: PARAM_INDEX_ID	The id of the indexed document.		String
indexName (producer) Constant: PARAM_INDEX_NAME	The name of the index to act against.		String
documentClass (producer) Constant: PARAM_DOCUMENT_CLASS	The full qualified name of the class of the document to unmarshall.	Object Node	Class
waitForActiveShards (producer) Constant: PARAM_WAIT_FOR_ACTIVE_SHARDS	The index creation waits for the write consistency number of shards to be available.		Integer

Name	Description	Default	Type
scrollKeepAliveMs (producer) Constant: PARAM_SCROLL_KEEP_ALIVE_MS	The starting index of the response.		Integer
useScroll (producer) Constant: PARAM_SCROLL	Set to true to enable scroll usage.		Boolean
size (producer) Constant: PARAM_SIZE	The size of the response.		Integer
from (producer) Constant: PARAM_FROM	The starting index of the response.		Integer

34.7. MESSAGE OPERATIONS

The following ElasticSearch operations are currently supported. Simply set an endpoint URI option or exchange header with a key of "operation" and a value set to one of the following. Some operations also require other parameters or the message body to be set.

operation	message body	description
Index	Map, String, byte[], Reader, InputStream or IndexRequest.Builder content to index	Adds content to an index and returns the content's indexId in the body. You can set the name of the target index by setting the message header with the key "indexName". You can set the indexId by setting the message header with the key "indexId".

operation	message body	description
GetById	String or GetRequest.Builder index id of content to retrieve	Retrieves the document corresponding to the given index id and returns a <code>GetResponse</code> object in the body. You can set the name of the target index by setting the message header with the key "indexName". You can set the type of document by setting the message header with the key "documentClass".
Delete	String or DeleteRequest.Builder index id of content to delete	Deletes the specified indexName and returns a <code>Result</code> object in the body. You can set the name of the target index by setting the message header with the key "indexName".
DeleteIndex	String or DeleteIndexRequest.Builder index name of the index to delete	Deletes the specified indexName and returns a status code in the body. You can set the name of the target index by setting the message header with the key "indexName".

operation	message body	description
Bulk	Iterable or BulkRequest.Builder of any type that is already accepted (DeleteOperation.Builder for delete operation, UpdateOperation.Builder for update operation, CreateOperation.Builder for create operation, byte[], InputStream, String, Reader, Map or any document type for index operation)	Adds/Updates/Deletes content from/to an index and returns a List<BulkResponseItem> object in the body You can set the name of the target index by setting the message header with the key "indexName".

operation	message body	description
Search	Map, String or SearchRequest.Builder	Search the content with the map of query string. You can set the name of the target index by setting the message header with the key "indexName". You can set the number of hits to return by setting the message header with the key "size". You can set the starting document offset by setting the message header with the key "from".
MultiSearch	MsearchRequest.Builder	Multiple search in one
MultiGet	Iterable<String> or MgetRequest.Builder the id of the document to retrieve	Multiple get in one You can set the name of the target index by setting the message header with the key "indexName".
Exists	None	Checks whether the index exists or not and returns a Boolean flag in the body. You must set the name of the target index by setting the message header with the key "indexName".
Update	byte[], InputStream, String, Reader, Map or any document type content to update	Updates content to an index and returns the content's indexId in the body. You can set the name of the target index by setting the message header with the key "indexName". You can set the indexId by setting the message header with the key "indexId".
Ping	None	Pings the Elasticsearch cluster and returns true if the ping succeeded, false otherwise

34.8. CONFIGURE THE COMPONENT AND ENABLE BASIC AUTHENTICATION

To use the Elasticsearch component it has to be configured with a minimum configuration.

```
ElasticsearchComponent elasticsearchComponent = new ElasticsearchComponent();
elasticsearchComponent.setHostAddresses("myelkhost:9200");
camelContext.addComponent("elasticsearch", elasticsearchComponent);
```

For basic authentication with elasticsearch or using reverse http proxy in front of the elasticsearch cluster, simply setup basic authentication and SSL on the component like the example below

```
ElasticsearchComponent elasticsearchComponent = new ElasticsearchComponent();
elasticsearchComponent.setHostAddresses("myelkhost:9200");
elasticsearchComponent.setUser("elkuser");
elasticsearchComponent.setPassword("secure!!");
elasticsearchComponent.setEnableSSL(true);
elasticsearchComponent.setCertificatePath(certPath);

camelContext.addComponent("elasticsearch", elasticsearchComponent);
```

34.9. INDEX EXAMPLE

Below is a simple INDEX example

```
from("direct:index")
  .to("elasticsearch://elasticsearch?operation=Index&indexName=twitter");

<route>
  <from uri="direct:index"/>
  <to uri="elasticsearch://elasticsearch?operation=Index&indexName=twitter"/>
</route>
```

For this operation you need to specify a `indexId` header.

A client would simply need to pass a body message containing a Map to the route. The result body contains the `indexId` created.

```
Map<String, String> map = new HashMap<String, String>();
map.put("content", "test");
String indexId = template.requestBody("direct:index", map, String.class);
```

34.10. SEARCH EXAMPLE

Searching on specific field(s) and value use the Operation `Search`. Pass in the query JSON String or the Map

```
from("direct:search")
  .to("elasticsearch://elasticsearch?operation=Search&indexName=twitter");

<route>
```

```

    <from uri="direct:search"/>
    <to uri="elasticsearch://elasticsearch?operation=Search&indexName=twitter"/>
</route>

```

```

String query = "{\"query\":{\"match\":{\"doc.content\":\"new release of ApacheCamel\"}}}";
HitsMetadata<?> response = template.requestBody("direct:search", query, HitsMetadata.class);

```

Search on specific field(s) using Map.

```

Map<String, Object> actualQuery = new HashMap<>();
actualQuery.put("doc.content", "new release of ApacheCamel");

Map<String, Object> match = new HashMap<>();
match.put("match", actualQuery);

Map<String, Object> query = new HashMap<>();
query.put("query", match);
HitsMetadata<?> response = template.requestBody("direct:search", query, HitsMetadata.class);

```

Search using Elasticsearch scroll api in order to fetch all results.

```

from("direct:search")
.to("elasticsearch://elasticsearch?
operation=Search&indexName=twitter&useScroll=true&scrollKeepAliveMs=30000");

```

```

<route>
  <from uri="direct:search"/>
  <to uri="elasticsearch://elasticsearch?
operation=Search&indexName=twitter&useScroll=true&scrollKeepAliveMs=30000"/>
</route>

```

```

String query = "{\"query\":{\"match\":{\"doc.content\":\"new release of ApacheCamel\"}}}";
try (ElasticsearchScrollRequestIterator response = template.requestBody("direct:search", query,
ElasticsearchScrollRequestIterator.class)) {
    // do something smart with results
}

```

can also be used.

```

from("direct:search")
.to("elasticsearch://elasticsearch?
operation=Search&indexName=twitter&useScroll=true&scrollKeepAliveMs=30000")
.split()
.body()
.streaming()
.to("mock:output")
.end();

```

34.11. MULTISEARCH EXAMPLE

MultiSearching on specific field(s) and value use the Operation `MultiSearch`. Pass in the `MultiSearchRequest` instance

```
from("direct:multiSearch")
  .to("elasticsearch://elasticsearch?operation=MultiSearch");
```

```
<route>
  <from uri="direct:multiSearch"/>
  <to uri="elasticsearch://elasticsearch?operation=MultiSearch"/>
</route>
```

MultiSearch on specific field(s)

```
MsearchRequest.Builder builder = new MsearchRequest.Builder().index("twitter").searches(
    new RequestItem.Builder().header(new MultisearchHeader.Builder().build())
        .body(new MultisearchBody.Builder().query(b -> b.matchAll(x -> x)).build()).build(),
    new RequestItem.Builder().header(new MultisearchHeader.Builder().build())
        .body(new MultisearchBody.Builder().query(b -> b.matchAll(x -> x)).build()).build());
List<MultiSearchResponseItem<?>> response = template.requestBody("direct:multiSearch", builder,
    List.class);
```

34.12. DOCUMENT TYPE

For all the search operations, it is possible to indicate the type of document to retrieve in order to get the result already unmarshalled with the expected type.

The document type can be set using the header "documentClass" or via the uri parameter of the same name.

34.13. USING CAMEL ELASTICSEARCH WITH SPRING BOOT

When you use **camel-elasticsearch-starter** with Spring Boot v2, then you must declare the following dependency in your own **pom.xml**.

```
<dependency>
  <groupId>jakarta.json</groupId>
  <artifactId>jakarta.json-api</artifactId>
  <version>2.0.2</version>
</dependency>
```

This is needed because Spring Boot v2 provides jakarta.json-api:1.1.6, and Elasticsearch requires to use json-api v2.

34.13.1. Use RestClient provided by Spring Boot

By default Spring Boot will auto configure an Elasticsearch RestClient that will be used by camel, it is possible to customize the client with the following basic properties:

```
spring.elasticsearch.uris=myelkhost:9200
spring.elasticsearch.username=elkuser
spring.elasticsearch.password=secure!!
```

More information can be found in [application-properties.data.spring.elasticsearch.connection-timeout](#).

34.13.2. Disable Sniffer when using Spring Boot

When Spring Boot is on the classpath the Sniffer client for Elasticsearch is enabled by default. This option can be disabled in the Spring Boot Configuration:

```
spring:
  autoconfigure:
    exclude:
      org.springframework.boot.autoconfigure.elasticsearch.ElasticsearchRestClientAutoConfiguration
```

34.14. SPRING BOOT AUTO-CONFIGURATION

The component supports 15 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.elasticsearch.automated-enabled</code>	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
<code>camel.component.elasticsearch.certificate-path</code>	The path of the self-signed certificate to use to access to Elasticsearch.		String
<code>camel.component.elasticsearch.client</code>	To use an existing configured Elasticsearch client, instead of creating a client per endpoint. This allow to customize the client with specific settings. The option is a <code>org.elasticsearch.client.RestClient</code> type.		RestClient
<code>camel.component.elasticsearch.connection-timeout</code>	The time in ms to wait before connection will timeout.	30000	Integer
<code>camel.component.elasticsearch.enable-ssl</code>	Enable SSL.	false	Boolean
<code>camel.component.elasticsearch.enable-sniffer</code>	Enable automatically discover nodes from a running Elasticsearch cluster. If this option is used in conjunction with Spring Boot then it's managed by the Spring Boot configuration (see: Disable Sniffer in Spring Boot).	false	Boolean
<code>camel.component.elasticsearch.enabled</code>	Whether to enable auto configuration of the elasticsearch component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.elasticsearch.host-addresses	Comma separated list with ip:port formatted remote transport addresses to use. The ip and port options must be left blank for hostAddresses to be considered instead.		String
camel.component.elasticsearch.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.elasticsearch.max-retry-timeout	The time in ms before retry.	30000	Integer
camel.component.elasticsearch.password	Password for authenticate.		String
camel.component.elasticsearch.sniff-after-failure-delay	The delay of a sniff execution scheduled after a failure (in milliseconds).	60000	Integer
camel.component.elasticsearch.sniffer-interval	The interval between consecutive ordinary sniff executions in milliseconds. Will be honoured when sniffOnFailure is disabled or when there are no failures between consecutive sniff executions.	30000 0	Integer
camel.component.elasticsearch.socket-timeout	The timeout in ms to wait before the socket will timeout.	30000	Integer
camel.component.elasticsearch.user	Basic authenticate user.		String

CHAPTER 35. EXCHANGEPROPERTY

The ExchangeProperty Expression Language allows you to extract values of named exchange properties.

35.1. DEPENDENCIES

The ExchangeProperty language is part of **camel-core**.

When using **exchangeProperty** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-core-starter</artifactId>
</dependency>
```

35.2. EXCHANGE PROPERTY OPTIONS

The ExchangeProperty language supports 1 options, which are listed below.

Name	Default	Java Type	Description
trim		Boolean	Whether to trim the value to remove leading and trailing whitespaces and line breaks.

35.3. EXAMPLE

The **recipientList** EIP can utilize a exchangeProperty like:

```
<route>
  <from uri="direct:a" />
  <recipientList>
    <exchangeProperty>myProperty</exchangeProperty>
  </recipientList>
</route>
```

In this case, the list of recipients are contained in the property 'myProperty'.

And the same example in Java DSL:

```
from("direct:a").recipientList(exchangeProperty("myProperty"));
```

35.4. SPRING BOOT AUTO-CONFIGURATION

The component supports 147 options, which are listed below.

Name	Description	Default	Type
<code>camel.cloud.consul.service-discovery.acl-token</code>	Sets the ACL token to be used with Consul.		String
<code>camel.cloud.consul.service-discovery.block-seconds</code>	The seconds to wait for a watch event, default 10 seconds.	10	Integer
<code>camel.cloud.consul.service-discovery.configurations</code>	Define additional configuration definitions.		Map
<code>camel.cloud.consul.service-discovery.connect-timeout-millis</code>	Connect timeout for OkHttpClient.		Long
<code>camel.cloud.consul.service-discovery.datacenter</code>	The data center.		String
<code>camel.cloud.consul.service-discovery.enabled</code>	Enable the component.	true	Boolean
<code>camel.cloud.consul.service-discovery.password</code>	Sets the password to be used for basic authentication.		String
<code>camel.cloud.consul.service-discovery.properties</code>	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in <code>com.netflix.client.config.CommonClientConfigKey</code> .		Map
<code>camel.cloud.consul.service-discovery.read-timeout-millis</code>	Read timeout for OkHttpClient.		Long
<code>camel.cloud.consul.service-discovery.url</code>	The Consul agent URL.		String

Name	Description	Default	Type
<code>camel.cloud.consul.service-discovery.username</code>	Sets the username to be used for basic authentication.		String
<code>camel.cloud.consul.service-discovery.write-timeout-millis</code>	Write timeout for OkHttpClient.		Long
<code>camel.cloud.dns.service-discovery.configurations</code>	Define additional configuration definitions.		Map
<code>camel.cloud.dns.service-discovery.domain</code>	The domain name;.		String
<code>camel.cloud.dns.service-discovery.enabled</code>	Enable the component.	true	Boolean
<code>camel.cloud.dns.service-discovery.properties</code>	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in <code>com.netflix.client.config.CommonClientConfigKey</code> .		Map
<code>camel.cloud.dns.service-discovery.proto</code>	The transport protocol of the desired service.	<code>_tcp</code>	String
<code>camel.cloud.etcd.service-discovery.configurations</code>	Define additional configuration definitions.		Map
<code>camel.cloud.etcd.service-discovery.enabled</code>	Enable the component.	true	Boolean
<code>camel.cloud.etcd.service-discovery.password</code>	The password to use for basic authentication.		String

Name	Description	Default	Type
camel.cloud.etcd.service-discovery.properties	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in <code>com.netflix.client.config.CommonClientConfigKey</code> .		Map
camel.cloud.etcd.service-discovery.service-path	The path to look for for service discovery.	<code>/services/</code>	String
camel.cloud.etcd.service-discovery.timeout	To set the maximum time an action could take to complete.		Long
camel.cloud.etcd.service-discovery.type	To set the discovery type, valid values are on-demand and watch.	on-demand	String
camel.cloud.etcd.service-discovery.uris	The URIs the client can connect to.		String
camel.cloud.etcd.service-discovery.user-name	The user name to use for basic authentication.		String
camel.cloud.kubernetes.service-discovery.api-version	Sets the API version when using client lookup.		String
camel.cloud.kubernetes.service-discovery.ca-cert-data	Sets the Certificate Authority data when using client lookup.		String
camel.cloud.kubernetes.service-discovery.ca-cert-file	Sets the Certificate Authority data that are loaded from the file when using client lookup.		String
camel.cloud.kubernetes.service-discovery.client-cert-data	Sets the Client Certificate data when using client lookup.		String

Name	Description	Default	Type
<code>camel.cloud.kubernetes.service-discovery.client-cert-file</code>	Sets the Client Certificate data that are loaded from the file when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.client-key-algo</code>	Sets the Client Keystore algorithm, such as RSA when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.client-key-data</code>	Sets the Client Keystore data when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.client-key-file</code>	Sets the Client Keystore data that are loaded from the file when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.client-key-passphrase</code>	Sets the Client Keystore passphrase when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.configurations</code>	Define additional configuration definitions.		Map
<code>camel.cloud.kubernetes.service-discovery.dns-domain</code>	Sets the DNS domain to use for DNS lookup.		String
<code>camel.cloud.kubernetes.service-discovery.enabled</code>	Enable the component.	true	Boolean

Name	Description	Default	Type
<code>camel.cloud.kubernetes.service-discovery.lookup</code>	How to perform service lookup. Possible values: client, dns, environment. When using client, then the client queries the kubernetes master to obtain a list of active pods that provides the service, and then random (or round robin) select a pod. When using dns the service name is resolved as name.namespace.svc.dnsDomain. When using dnssrv the service name is resolved with SRV query forsvc... When using environment then environment variables are used to lookup the service. By default environment is used.	environment	String
<code>camel.cloud.kubernetes.service-discovery.master-url</code>	Sets the URL to the master when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.namespace</code>	Sets the namespace to use. Will by default use namespace from the ENV variable KUBERNETES_MASTER.		String
<code>camel.cloud.kubernetes.service-discovery.oauth-token</code>	Sets the OAUTH token for authentication (instead of username/password) when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.password</code>	Sets the password for authentication when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.port-name</code>	Sets the Port Name to use for DNS/DNSSRV lookup.		String
<code>camel.cloud.kubernetes.service-discovery.port-protocol</code>	Sets the Port Protocol to use for DNS/DNSSRV lookup.		String
<code>camel.cloud.kubernetes.service-discovery.properties</code>	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in com.netflix.client.config.CommonClientConfigKey.		Map

Name	Description	Default	Type
<code>camel.cloud.kubernetes.service-discovery.trust-certs</code>	Sets whether to turn on trust certificate check when using client lookup.	false	Boolean
<code>camel.cloud.kubernetes.service-discovery.username</code>	Sets the username for authentication when using client lookup.		String
<code>camel.cloud.ribbon.load-balancer.client-name</code>	Sets the Ribbon client name.		String
<code>camel.cloud.ribbon.load-balancer.configurations</code>	Define additional configuration definitions.		Map
<code>camel.cloud.ribbon.load-balancer.enabled</code>	Enable the component.	true	Boolean
<code>camel.cloud.ribbon.load-balancer.namespace</code>	The namespace.		String
<code>camel.cloud.ribbon.load-balancer.password</code>	The password.		String
<code>camel.cloud.ribbon.load-balancer.properties</code>	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in <code>com.netflix.client.config.CommonClientConfigKey</code> .		Map
<code>camel.cloud.ribbon.load-balancer.username</code>	The username.		String

Name	Description	Default	Type
camel.hystrix.allow-maximum-size-to-diverge-from-core-size	Allows the configuration for <code>maximumSize</code> to take effect. That value can then be equal to, or higher, than <code>coreSize</code> .	false	Boolean
camel.hystrix.circuit-breaker-enabled	Whether to use a <code>HystrixCircuitBreaker</code> or not. If false no circuit-breaker logic will be used and all requests permitted. This is similar in effect to <code>circuitBreakerForceClosed()</code> except that continues tracking metrics and knowing whether it should be open/closed, this property results in not even instantiating a circuit-breaker.	true	Boolean
camel.hystrix.circuit-breaker-error-threshold-percentage	Error percentage threshold (as whole number such as 50) at which point the circuit breaker will trip open and reject requests. It will stay tripped for the duration defined in <code>circuitBreakerSleepWindowInMilliseconds</code> ; The error percentage this is compared against comes from <code>HystrixCommandMetrics.getHealthCounts()</code> .	50	Integer
camel.hystrix.circuit-breaker-force-closed	If true the <code>HystrixCircuitBreaker#allowRequest()</code> will always return true to allow requests regardless of the error percentage from <code>HystrixCommandMetrics.getHealthCounts()</code> . The <code>circuitBreakerForceOpen()</code> property takes precedence so if it set to true this property does nothing.	false	Boolean
camel.hystrix.circuit-breaker-force-open	If true the <code>HystrixCircuitBreaker.allowRequest()</code> will always return false, causing the circuit to be open (tripped) and reject all requests. This property takes precedence over <code>circuitBreakerForceClosed()</code> ;	false	Boolean
camel.hystrix.circuit-breaker-request-volume-threshold	Minimum number of requests in the <code>metricsRollingStatisticalWindowInMilliseconds()</code> that must exist before the <code>HystrixCircuitBreaker</code> will trip. If below this number the circuit will not trip regardless of error percentage.	20	Integer
camel.hystrix.circuit-breaker-sleep-window-in-milliseconds	The time in milliseconds after a <code>HystrixCircuitBreaker</code> trips open that it should wait before trying requests again.	5000	Integer
camel.hystrix.configurations	Define additional configuration definitions.		Map

Name	Description	Default	Type
camel.hystrix.core-pool-size	Core thread-pool size that gets passed to <code>java.util.concurrent.ThreadPoolExecutor#setCorePoolSize(int)</code> .	10	Integer
camel.hystrix.enabled	Enable the component.	true	Boolean
camel.hystrix.execution-isolation-semaphore-max-concurrent-requests	Number of concurrent requests permitted to <code>HystrixCommand.run()</code> . Requests beyond the concurrent limit will be rejected. Applicable only when <code>executionIsolationStrategy == SEMAPHORE</code> .	20	Integer
camel.hystrix.execution-isolation-strategy	What isolation strategy <code>HystrixCommand.run()</code> will be executed with. If <code>THREAD</code> then it will be executed on a separate thread and concurrent requests limited by the number of threads in the thread-pool. If <code>SEMAPHORE</code> then it will be executed on the calling thread and concurrent requests limited by the semaphore count.	THREAD	String
camel.hystrix.execution-isolation-thread-interrupt-on-timeout	Whether the execution thread should attempt an interrupt (using <code>Future#cancel()</code>) when a thread times out. Applicable only when <code>executionIsolationStrategy() == THREAD</code> .	true	Boolean
camel.hystrix.execution-timeout-enabled	Whether the timeout mechanism is enabled for this command.	true	Boolean
camel.hystrix.execution-timeout-in-milliseconds	Time in milliseconds at which point the command will timeout and halt execution. If <code>executionIsolationThreadInterruptOnTimeout == true</code> and the command is thread-isolated, the executing thread will be interrupted. If the command is semaphore-isolated and a <code>HystrixObservableCommand</code> , that command will get unsubscribed.	1000	Integer
camel.hystrix.fallback-ack-enabled	Whether <code>HystrixCommand.getFallback()</code> should be attempted when failure occurs.	true	Boolean
camel.hystrix.fallback-isolation-semaphore-max-concurrent-requests	Number of concurrent requests permitted to <code>HystrixCommand.getFallback()</code> . Requests beyond the concurrent limit will fail-fast and not attempt retrieving a fallback.	10	Integer

Name	Description	Default	Type
camel.hystrix.group-key	Sets the group key to use. The default value is CamelHystrix.	Camel Hystrix	String
camel.hystrix.keep-alive-time	Keep-alive time in minutes that gets passed to <code>ThreadPoolExecutor#setKeepAliveTime(long, TimeUnit)</code> .	1	Integer
camel.hystrix.max-queue-size	Max queue size that gets passed to <code>BlockingQueue</code> in <code>HystrixConcurrencyStrategy.getBlockingQueue(int)</code> . This should only affect the instantiation of a threadpool - it is not eligible to change a queue size on the fly. For that, use <code>queueSizeRejectionThreshold()</code> .	-1	Integer
camel.hystrix.maximum-size	Maximum thread-pool size that gets passed to <code>ThreadPoolExecutor#setMaximumPoolSize(int)</code> . This is the maximum amount of concurrency that can be supported without starting to reject <code>HystrixCommands</code> . Please note that this setting only takes effect if you also set <code>allowMaximumSizeToDivergeFromCoreSize</code> .	10	Integer
camel.hystrix.metrics-health-snapshot-interval-in-milliseconds	Time in milliseconds to wait between allowing health snapshots to be taken that calculate success and error percentages and affect <code>HystrixCircuitBreaker.isOpen()</code> status. On high-volume circuits the continual calculation of error percentage can become CPU intensive thus this controls how often it is calculated.	500	Integer
camel.hystrix.metrics-rolling-percentile-bucket-size	Maximum number of values stored in each bucket of the rolling percentile. This is passed into <code>HystrixRollingPercentile</code> inside <code>HystrixCommandMetrics</code> .	10	Integer
camel.hystrix.metrics-rolling-percentile-enabled	Whether percentile metrics should be captured using <code>HystrixRollingPercentile</code> inside <code>HystrixCommandMetrics</code> .	true	Boolean
camel.hystrix.metrics-rolling-percentile-window-buckets	Number of buckets the rolling percentile window is broken into. This is passed into <code>HystrixRollingPercentile</code> inside <code>HystrixCommandMetrics</code> .	6	Integer

Name	Description	Default	Type
camel.hystrix.metrics-rolling-percentile-window-in-milliseconds	Duration of percentile rolling window in milliseconds. This is passed into HystrixRollingPercentile inside HystrixCommandMetrics.	10000	Integer
camel.hystrix.metrics-rolling-statistical-window-buckets	Number of buckets the rolling statistical window is broken into. This is passed into HystrixRollingNumber inside HystrixCommandMetrics.	10	Integer
camel.hystrix.metrics-rolling-statistical-window-in-milliseconds	This property sets the duration of the statistical rolling window, in milliseconds. This is how long metrics are kept for the thread pool. The window is divided into buckets and rolls by those increments.	10000	Integer
camel.hystrix.queue-size-rejection-threshold	Queue size rejection threshold is an artificial max size at which rejections will occur even if maxQueueSize has not been reached. This is done because the maxQueueSize of a BlockingQueue can not be dynamically changed and we want to support dynamically changing the queue size that affects rejections. This is used by HystrixCommand when queuing a thread for execution.	5	Integer
camel.hystrix.request-log-enabled	Whether HystrixCommand execution and events should be logged to HystrixRequestLog.	true	Boolean
camel.hystrix.thread-pool-key	Sets the thread pool key to use. Will by default use the same value as groupKey has been configured to use.	Camel Hystrix	String
camel.hystrix.thread-pool-rolling-number-statistical-window-buckets	Number of buckets the rolling statistical window is broken into. This is passed into HystrixRollingNumber inside each HystrixThreadPoolMetrics instance.	10	Integer
camel.hystrix.thread-pool-rolling-number-statistical-window-in-milliseconds	Duration of statistical rolling window in milliseconds. This is passed into HystrixRollingNumber inside each HystrixThreadPoolMetrics instance.	10000	Integer
camel.language.constant.enabled	Whether to enable auto configuration of the constant language. This is enabled by default.		Boolean

Name	Description	Default	Type
<code>camel.language.constant.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
<code>camel.language.csimple.enabled</code>	Whether to enable auto configuration of the csimple language. This is enabled by default.		Boolean
<code>camel.language.csimple.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
<code>camel.language.exchangeproperty.enabled</code>	Whether to enable auto configuration of the exchangeProperty language. This is enabled by default.		Boolean
<code>camel.language.exchangeproperty.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
<code>camel.language.file.enabled</code>	Whether to enable auto configuration of the file language. This is enabled by default.		Boolean
<code>camel.language.file.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
<code>camel.language.header.enabled</code>	Whether to enable auto configuration of the header language. This is enabled by default.		Boolean
<code>camel.language.header.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
<code>camel.language.ref.enabled</code>	Whether to enable auto configuration of the ref language. This is enabled by default.		Boolean
<code>camel.language.ref.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
<code>camel.language.simple.enabled</code>	Whether to enable auto configuration of the simple language. This is enabled by default.		Boolean
<code>camel.language.simple.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
<code>camel.language.tokenize.enabled</code>	Whether to enable auto configuration of the tokenize language. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.language.tokenize.group-delimiter	Sets the delimiter to use when grouping. If this has not been set then token will be used as the delimiter.		String
camel.language.tokenize.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
camel.resilience4j.automatic-transition-from-open-to-half-open-enabled	Enables automatic transition from OPEN to HALF_OPEN state once the waitDurationInOpenState has passed.	false	Boolean
camel.resilience4j.circuit-breaker-ref	Refers to an existing io.github.resilience4j.circuitbreaker.CircuitBreaker instance to lookup and use from the registry. When using this, then any other circuit breaker options are not in use.		String
camel.resilience4j.config-ref	Refers to an existing io.github.resilience4j.circuitbreaker.CircuitBreakerConfig instance to lookup and use from the registry.		String
camel.resilience4j.configurations	Define additional configuration definitions.		Map
camel.resilience4j.enabled	Enable the component.	true	Boolean
camel.resilience4j.failure-rate-threshold	Configures the failure rate threshold in percentage. If the failure rate is equal or greater than the threshold the CircuitBreaker transitions to open and starts short-circuiting calls. The threshold must be greater than 0 and not greater than 100. Default value is 50 percentage.		Float
camel.resilience4j.minimum-number-of-calls	Configures the minimum number of calls which are required (per sliding window period) before the CircuitBreaker can calculate the error rate. For example, if minimumNumberOfCalls is 10, then at least 10 calls must be recorded, before the failure rate can be calculated. If only 9 calls have been recorded the CircuitBreaker will not transition to open even if all 9 calls have failed. Default minimumNumberOfCalls is 100.	100	Integer

Name	Description	Default	Type
camel.resilience4j.permitted-number-of-calls-in-half-open-state	Configures the number of permitted calls when the CircuitBreaker is half open. The size must be greater than 0. Default size is 10.	10	Integer
camel.resilience4j.sliding-window-size	Configures the size of the sliding window which is used to record the outcome of calls when the CircuitBreaker is closed. slidingWindowSize configures the size of the sliding window. Sliding window can either be count-based or time-based. If slidingWindowType is COUNT_BASED, the last slidingWindowSize calls are recorded and aggregated. If slidingWindowType is TIME_BASED, the calls of the last slidingWindowSize seconds are recorded and aggregated. The slidingWindowSize must be greater than 0. The minimumNumberOfCalls must be greater than 0. If the slidingWindowType is COUNT_BASED, the minimumNumberOfCalls cannot be greater than slidingWindowSize. If the slidingWindowType is TIME_BASED, you can pick whatever you want. Default slidingWindowSize is 100.	100	Integer
camel.resilience4j.sliding-window-type	Configures the type of the sliding window which is used to record the outcome of calls when the CircuitBreaker is closed. Sliding window can either be count-based or time-based. If slidingWindowType is COUNT_BASED, the last slidingWindowSize calls are recorded and aggregated. If slidingWindowType is TIME_BASED, the calls of the last slidingWindowSize seconds are recorded and aggregated. Default slidingWindowType is COUNT_BASED.	COUNT_BASED	String
camel.resilience4j.slow-call-duration-threshold	Configures the duration threshold (seconds) above which calls are considered as slow and increase the slow calls percentage. Default value is 60 seconds.	60	Integer
camel.resilience4j.slow-call-rate-threshold	Configures a threshold in percentage. The CircuitBreaker considers a call as slow when the call duration is greater than slowCallDurationThreshold. When the percentage of slow calls is equal or greater the threshold, the CircuitBreaker transitions to open and starts short-circuiting calls. The threshold must be greater than 0 and not greater than 100. Default value is 100 percentage which means that all recorded calls must be slower than slowCallDurationThreshold.		Float

Name	Description	Default	Type
camel.resilience4j.wait-duration-in-open-state	Configures the wait duration (in seconds) which specifies how long the CircuitBreaker should stay open, before it switches to half open. Default value is 60 seconds.	60	Integer
camel.resilience4j.writable-stack-trace-enabled	Enables writable stack traces. When set to false, <code>Exception.getStackTrace</code> returns a zero length array. This may be used to reduce log spam when the circuit breaker is open as the cause of the exceptions is already known (the circuit breaker is short-circuiting calls).	true	Boolean
camel.rest.api-component	The name of the Camel component to use as the REST API (such as swagger) If no API Component has been explicit configured, then Camel will lookup if there is a Camel component responsible for servicing and generating the REST API documentation, or if a <code>org.apache.camel.spi.RestApiProcessorFactory</code> is registered in the registry. If either one is found, then that is being used.		String
camel.rest.api-context-path	Sets a leading API context-path the REST API services will be using. This can be used when using components such as camel-servlet where the deployed web application is deployed using a context-path.		String
camel.rest.api-context-route-id	Sets the route id to use for the route that services the REST API. The route will by default use an auto assigned route id.		String
camel.rest.api-host	To use an specific hostname for the API documentation (eg swagger) This can be used to override the generated host with this configured hostname.		String
camel.rest.api-property	Allows to configure as many additional properties for the api documentation (swagger). For example set property <code>api.title</code> to my cool stuff.		Map
camel.rest.api-vendor-extension	Whether vendor extension is enabled in the Rest APIs. If enabled then Camel will include additional information as vendor extension (eg keys starting with x-) such as route ids, class names etc. Not all 3rd party API gateways and tools supports vendor-extensions when importing your API docs.	false	Boolean
camel.rest.binding-mode	Sets the binding mode to use. The default value is off.		RestBindingMode

Name	Description	Default	Type
camel.rest.client-request-validation	Whether to enable validation of the client request to check whether the Content-Type and Accept headers from the client is supported by the Rest-DSL configuration of its consumes/produces settings. This can be turned on, to enable this check. In case of validation error, then HTTP Status codes 415 or 406 is returned. The default value is false.	false	Boolean
camel.rest.component	The Camel Rest component to use for the REST transport (consumer), such as netty-http, jetty, servlet, undertow. If no component has been explicit configured, then Camel will lookup if there is a Camel component that integrates with the Rest DSL, or if a org.apache.camel.spi.RestConsumerFactory is registered in the registry. If either one is found, then that is being used.		String
camel.rest.component-property	Allows to configure as many additional properties for the rest component in use.		Map
camel.rest.consumer-property	Allows to configure as many additional properties for the rest consumer in use.		Map
camel.rest.context-path	Sets a leading context-path the REST services will be using. This can be used when using components such as camel-servlet where the deployed web application is deployed using a context-path. Or for components such as camel-jetty or camel-netty-http that includes a HTTP server.		String
camel.rest.cors-headers	Allows to configure custom CORS headers.		Map
camel.rest.data-format-property	Allows to configure as many additional properties for the data formats in use. For example set property prettyPrint to true to have json outputted in pretty mode. The properties can be prefixed to denote the option is only for either JSON or XML and for either the IN or the OUT. The prefixes are: json.in. json.out. xml.in. xml.out. For example a key with value xml.out.mustBeJAXBELEMENT is only for the XML data format for the outgoing. A key without a prefix is a common key for all situations.		Map
camel.rest.enable-cors	Whether to enable CORS headers in the HTTP response. The default value is false.	false	Boolean

Name	Description	Default	Type
camel.rest.endpoint-property	Allows to configure as many additional properties for the rest endpoint in use.		Map
camel.rest.host	The hostname to use for exposing the REST service.		String
camel.rest.hostname-resolver	If no hostname has been explicit configured, then this resolver is used to compute the hostname the REST service will be using.		RestHostNameResolver
camel.rest.json-data-format	Name of specific json data format to use. By default json-jackson will be used. Important: This option is only for setting a custom name of the data format, not to refer to an existing data format instance.		String
camel.rest.port	The port number to use for exposing the REST service. Notice if you use servlet component then the port number configured here does not apply, as the port number in use is the actual port number the servlet component is using. eg if using Apache Tomcat its the tomcat http port, if using Apache Karaf its the HTTP service in Karaf that uses port 8181 by default etc. Though in those situations setting the port number here, allows tooling and JMX to know the port number, so its recommended to set the port number to the number that the servlet engine uses.		String
camel.rest.producer-api-doc	Sets the location of the api document (swagger api) the REST producer will use to validate the REST uri and query parameters are valid accordingly to the api document. This requires adding camel-swagger-java to the classpath, and any miss configuration will let Camel fail on startup and report the error(s). The location of the api document is loaded from classpath by default, but you can use file: or http: to refer to resources to load from file or http url.		String
camel.rest.producer-component	Sets the name of the Camel component to use as the REST producer.		String
camel.rest.scheme	The scheme to use for exposing the REST service. Usually http or https is supported. The default value is http.		String
camel.rest.skip-binding-on-error-code	Whether to skip binding on output if there is a custom HTTP error code header. This allows to build custom error messages that do not bind to json / xml etc, as success messages otherwise will do.	false	Boolean

Name	Description	Default	Type
<code>camel.rest.use-x-forward-headers</code>	Whether to use X-Forward headers for Host and related setting. The default value is true.	true	Boolean
<code>camel.rest.xml-data-format</code>	Name of specific XML data format to use. By default jaxb will be used. Important: This option is only for setting a custom name of the data format, not to refer to an existing data format instance.		String
<code>camel.rest.api-context-id-pattern</code>	Deprecated Sets an CamelContext id pattern to only allow Rest APIs from rest services within CamelContext's which name matches the pattern. The pattern name refers to the CamelContext name, to match on the current CamelContext only. For any other value, the pattern uses the rules from PatternHelper#matchPattern(String,String).		String
<code>camel.rest.api-context-listing</code>	Deprecated Sets whether listing of all available CamelContext's with REST services in the JVM is enabled. If enabled it allows to discover these contexts, if false then only the current CamelContext is in use.	false	Boolean

CHAPTER 36. FHIR

Both producer and consumer are supported

The FHIR component integrates with the [HAPI-FHIR](#) library which is an open-source implementation of the [FHIR](#) (Fast Healthcare Interoperability Resources) specification in Java.

36.1. DEPENDENCIES

When using **fhir** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>  
  <groupId>org.apache.camel.springboot</groupId>  
  <artifactId>camel-fhir-starter</artifactId>  
</dependency>
```

36.2. URI FORMAT

The FHIR Component uses the following URI format:

```
fhir://endpoint-prefix/endpoint?[options]
```

Endpoint prefix can be one of:

- capabilities
- create
- delete
- history
- load-page
- meta
- operation
- patch
- read
- search
- transaction
- update
- validate

36.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

36.3.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).
- directly in the Java code.

36.3.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

36.4. COMPONENT OPTIONS

The FHIR component supports 27 options, which are listed below.

Name	Description	Default	Type
------	-------------	---------	------

Name	Description	Default	Type
encoding (common)	Encoding to use for all request. Enum values: • JSON • XML		String
fhirVersion (common)	The FHIR Version to use. Enum values: • DSTU2 • DSTU2_HL7ORG • DSTU2_1 • DSTU3 • R4 • R5	R4	String
log (common)	Will log every requests and responses.	false	boolean
prettyPrint (common)	Pretty print all request.	false	boolean
serverUrl (common)	The FHIR server base URL.		String
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
client (advanced)	To use the custom client.		IGenericClient
clientFactory (advanced)	To use the custom client factory.		IRestfulClientFactory
compress (advanced)	Compresses outgoing (POST/PUT) contents to the GZIP format.	false	boolean
configuration (advanced)	To use the shared configuration.		FhirConfiguration
connectionTimeout (advanced)	How long to try and establish the initial TCP connection (in ms).	10000	Integer
deferModelScanning (advanced)	When this option is set, model classes will not be scanned for children until the child list for the given type is actually accessed.	false	boolean
fhirContext (advanced)	FhirContext is an expensive object to create. To avoid creating multiple instances, it can be set directly.		FhirContext
forceConformanceCheck (advanced)	Force conformance check.	false	boolean

Name	Description	Default	Type
sessionCookie (advanced)	HTTP session cookie to add to every request.		String
socketTimeout (advanced)	How long to block for individual read/write operations (in ms).	10000	Integer
summary (advanced)	Request that the server modify the response using the <code>_summary</code> param. Enum values: • COUNT • TEXT • DATA • TRUE • FALSE		String
validationMode (advanced)	When should Camel validate the FHIR Server's conformance statement. Enum values: • NEVER • ONCE	ONCE	String
proxyHost (proxy)	The proxy host.		String
proxyPassword (proxy)	The proxy password.		String
proxyPort (proxy)	The proxy port.		Integer
proxyUser (proxy)	The proxy username.		String
accessToken (security)	OAuth access token.		String
password (security)	Username to use for basic authentication.		String
username (security)	Username to use for basic authentication.		String

36.5. ENDPOINT OPTIONS

The FHIR endpoint is configured using URI syntax:

```
fhir:apiName/methodName
```

with the following path and query parameters:

36.5.1. Path Parameters (2 parameters)

Name	Description	Default	Type
apiName (common)	Required What kind of operation to perform. Enum values: • CAPABILITIES • CREATE • DELETE • HISTORY • LOAD_PAGE • META • OPERATION • PATCH • READ • SEARCH • TRANSACTION • UPDATE • VALIDATE		FhirApiName
methodName (common)	Required What sub operation to use for the selected operation.		String

36.5.2. Query Parameters (44 parameters)

Name	Description	Default	Type
------	-------------	---------	------

Name	Description	Default	Type
encoding (common)	Encoding to use for all request. Enum values: • JSON • XML		String
fhirVersion (common)	The FHIR Version to use. Enum values: • DSTU2 • DSTU2_HL7ORG • DSTU2_1 • DSTU3 • R4 • R5	R4	String
inBody (common)	Sets the name of a parameter to be passed in the exchange In Body.		String
log (common)	Will log every requests and responses.	false	boolean
prettyPrint (common)	Pretty print all request.	false	boolean
serverUrl (common)	The FHIR server base URL.		String
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean

Name	Description	Default	Type
exceptionHandler (consumer (advanced))	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at <code>WARN</code> or <code>ERROR</code> level and ignored.		<code>ExceptionHandler</code>
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • <code>InOnly</code> • <code>InOut</code> • <code>InOptionalOut</code>		<code>ExchangePattern</code>
pollStrategy (consumer (advanced))	A pluggable <code>org.apache.camel.PollingConsumerPollingStrategy</code> allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an <code>Exchange</code> have been created and being routed in Camel.		<code>PollingConsumerPollStrategy</code>
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow <code>CamelContext</code> and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
client (advanced)	To use the custom client.		<code>IGenericClient</code>
clientFactory (advanced)	To use the custom client factory.		<code>IRestfulClientFactory</code>
compress (advanced)	Compresses outgoing (POST/PUT) contents to the GZIP format.	false	boolean
connectionTimeout (advanced)	How long to try and establish the initial TCP connection (in ms).	10000	Integer

Name	Description	Default	Type
deferModelScanning (advanced)	When this option is set, model classes will not be scanned for children until the child list for the given type is actually accessed.	false	boolean
fhirContext (advanced)	FhirContext is an expensive object to create. To avoid creating multiple instances, it can be set directly.		FhirContext
forceConformanceCheck (advanced)	Force conformance check.	false	boolean
sessionCookie (advanced)	HTTP session cookie to add to every request.		String
socketTimeout (advanced)	How long to block for individual read/write operations (in ms).	10000	Integer
summary (advanced)	Request that the server modify the response using the <code>_summary</code> param. Enum values: ● COUNT ● TEXT ● DATA ● TRUE ● FALSE		String
validationMode (advanced)	When should Camel validate the FHIR Server's conformance statement. Enum values: ● NEVER ● ONCE	ONCE	String
proxyHost (proxy)	The proxy host.		String
proxyPassword (proxy)	The proxy password.		String
proxyPort (proxy)	The proxy port.		Integer

Name	Description	Default	Type
proxyUser (proxy)	The proxy username.		String
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.		int
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.		int
delay (scheduler)	Milliseconds before the next poll.	500	long
greedy (scheduler)	If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts.	1000	long
repeatCount (scheduler)	Specifies a maximum limit of number of fires. So if you set it to 1, the scheduler will only fire once. If you set it to 5, it will only fire five times. A value of zero or negative means fire forever.	0	long
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that. Enum values: ● TRACE ● DEBUG ● INFO ● WARN ● ERROR ● OFF	TRACE	LoggingLevel

Name	Description	Default	Type
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz component. Use value spring or quartz for built in scheduler.	none	Object
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for initialDelay and delay options. Enum values: • NANOSECONDS • MICROSECONDS • MILLISECONDS • SECONDS • MINUTES • HOURS • DAYS	MILLISECONDS	TimeUnit
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.	true	boolean
accessToken (security)	OAuth access token.		String
password (security)	Username to use for basic authentication.		String
username (security)	Username to use for basic authentication.		String

36.6. API PARAMETERS (13 APIS)

The @FHIR endpoint is an API based component and has additional parameters based on which API name and API method is used. The API name and API method is located in the endpoint URI as the **apiName/methodName** path parameters:

```
fhir:apiName/methodName
```

There are 13 API names as listed in the table below:

API Name	Type	Description
capabilities	Both	API to Fetch the capability statement for the server
create	Both	API for the create operation, which creates a new resource instance on the server
delete	Both	API for the delete operation, which performs a logical delete on a server resource
history	Both	API for the history method
load-page	Both	API that Loads the previous/next bundle of resources from a paged set, using the link specified in the link type=next tag within the atom bundle
meta	Both	API for the meta operations, which can be used to get, add and remove tags and other Meta elements from a resource or across the server
operation	Both	API for extended FHIR operations
patch	Both	API for the patch operation, which performs a logical patch on a server resource
read	Both	API method for read operations
search	Both	API to search for resources matching a given set of criteria
transaction	Both	API for sending a transaction (collection of resources) to the server to be executed as a single unit
update	Both	API for the update operation, which performs a logical delete on a server resource
validate	Both	API for validating resources

Each API is documented in the following sections to come.

36.6.1. API: capabilities

Both producer and consumer are supported

The capabilities API is defined in the syntax as follows:

```
fhir:capabilities/methodName?[parameters]
```

The method is listed in the table below, followed by detailed syntax for each method. (API methods can have a shorthand alias name which can be used in the syntax instead of the name)

Method	Description
ofType	Retrieve the conformance statement using the given model type

36.6.1.1. Method ofType

Signatures:

- ```
org.hl7.fhir.instance.model.api.IBaseConformance
ofType(Class<org.hl7.fhir.instance.model.api.IBaseConformance> type,
java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);
```

The fhir/ofType API method has the parameters listed in the table below:

| Parameter              | Description                                                                       | Type  |
|------------------------|-----------------------------------------------------------------------------------|-------|
| <b>extraParameters</b> | See ExtraParameters for a full list of parameters that can be passed, may be NULL | Map   |
| <b>type</b>            | The model type                                                                    | Class |

In addition to the parameters above, the fhir API can also use any of the [Query Parameters](#).

Any of the parameters can be provided in either the endpoint URI, or dynamically in a message header. The message header name must be of the format **CamelFhir.parameter**. The **inBody** parameter overrides message header, i.e. the endpoint parameter **inBody=myParameterNameHere** would override a **CamelFhir.myParameterNameHere** header.

### 36.6.2. API: create

#### Both producer and consumer are supported

The create API is defined in the syntax as follows:

```
fhir:create/methodName?[parameters]
```

The 1 method(s) is listed in the table below, followed by detailed syntax for each method. (API methods can have a shorthand alias name which can be used in the syntax instead of the name)

| Method                   | Description                           |
|--------------------------|---------------------------------------|
| <a href="#">resource</a> | Creates a IBaseResource on the server |

### 36.6.2.1. Method resource

Signatures:

- `ca.uhn.fhir.rest.api.MethodOutcome resource(String resourceAsString, String url, ca.uhn.fhir.rest.api.PreferReturnEnum preferReturn, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`
- `ca.uhn.fhir.rest.api.MethodOutcome resource(org.hl7.fhir.instance.model.api.IBaseResource resource, String url, ca.uhn.fhir.rest.api.PreferReturnEnum preferReturn, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`

The fhir/resource API method has the parameters listed in the table below:

| Parameter               | Description                                                                                                                                                                                                                                                                         | Type             |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| <b>extraParameters</b>  | See ExtraParameters for a full list of parameters that can be passed, may be NULL                                                                                                                                                                                                   | Map              |
| <b>preferReturn</b>     | Add a Prefer header to the request, which requests that the server include or suppress the resource body as a part of the result. If a resource is returned by the server it will be parsed and accessible to the client via <code>MethodOutcome#getResource()</code> , may be null | PreferReturnEnum |
| <b>resource</b>         | The resource to create                                                                                                                                                                                                                                                              | IBaseResource    |
| <b>resourceAsString</b> | The resource to create                                                                                                                                                                                                                                                              | String           |
| <b>url</b>              | The search URL to use. The format of this URL should be of the form <code>ResourceTypeParameters</code> , for example:<br><code>Patientname=Smith&amp;identifier=13.2.4.11.4%7C847366</code> , may be null                                                                          | String           |

In addition to the parameters above, the fhir API can also use any of the [Query Parameters](#).

Any of the parameters can be provided in either the endpoint URI, or dynamically in a message header. The message header name must be of the format **CamelFhir.parameter**. The **inBody** parameter overrides message header, i.e. the endpoint parameter **inBody=myParameterNameHere** would override a **CamelFhir.myParameterNameHere** header.

### 36.6.3. API: delete

Both producer and consumer are supported

The delete API is defined in the syntax as follows:

```
fhir:delete/methodName?[parameters]
```

The 3 method(s) is listed in the table below, followed by detailed syntax for each method. (API methods can have a shorthand alias name which can be used in the syntax instead of the name)

| Method                                   | Description                                                                                      |
|------------------------------------------|--------------------------------------------------------------------------------------------------|
| <a href="#">resource</a>                 | Deletes the given resource                                                                       |
| <a href="#">resourceById</a>             | Deletes the resource by resource type e                                                          |
| <a href="#">resourceConditionalByUrl</a> | Specifies that the delete should be performed as a conditional delete against a given search URL |

### 36.6.3.1. Method resource

Signatures:

- `org.hl7.fhir.instance.model.api.IBaseOperationOutcome resource(org.hl7.fhir.instance.model.api.IBaseResource resource, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`

The `fhir/resource` API method has the parameters listed in the table below:

| Parameter              | Description                                                                                    | Type                       |
|------------------------|------------------------------------------------------------------------------------------------|----------------------------|
| <b>extraParameters</b> | See <code>ExtraParameters</code> for a full list of parameters that can be passed, may be NULL | Map                        |
| <b>resource</b>        | The <code>IBaseResource</code> to delete                                                       | <code>IBaseResource</code> |

### 36.6.3.2. Method resourceById

Signatures:

- `org.hl7.fhir.instance.model.api.IBaseOperationOutcome resourceById(String type, String stringId, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`
- `org.hl7.fhir.instance.model.api.IBaseOperationOutcome resourceById(org.hl7.fhir.instance.model.api.IIdType id, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`

The `fhir/resourceById` API method has the parameters listed in the table below:

| Parameter              | Description                                                                       | Type    |
|------------------------|-----------------------------------------------------------------------------------|---------|
| <b>extraParameters</b> | See ExtraParameters for a full list of parameters that can be passed, may be NULL | Map     |
| <b>id</b>              | The IIdType referencing the resource                                              | IIdType |
| <b>stringId</b>        | It's id                                                                           | String  |
| <b>type</b>            | The resource type e.g Patient                                                     | String  |

### 36.6.3.3. Method resourceConditionalByUrl

Signatures:

- `org.hl7.fhir.instance.model.api.IBaseOperationOutcome resourceConditionalByUrl(String url, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`

The `fhir/resourceConditionalByUrl` API method has the parameters listed in the table below:

| Parameter              | Description                                                                                                                                                                                  | Type   |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|
| <b>extraParameters</b> | See ExtraParameters for a full list of parameters that can be passed, may be NULL                                                                                                            | Map    |
| <b>url</b>             | The search URL to use. The format of this URL should be of the form <code>ResourceTypeParameters</code> , for example:<br><code>Patientname=Smith&amp;identifier=13.2.4.11.4%7C847366</code> | String |

In addition to the parameters above, the `fhir` API can also use any of the [Query Parameters](#).

Any of the parameters can be provided in either the endpoint URI, or dynamically in a message header. The message header name must be of the format **CamelFhir.parameter**. The **inBody** parameter overrides message header, i.e. the endpoint parameter **inBody=myParameterNameHere** would override a **CamelFhir.myParameterNameHere** header.

### 36.6.4. API: history

**Both producer and consumer are supported**

The history API is defined in the syntax as follows:

```
fhir:history/methodName?[parameters]
```

The 3 method(s) is listed in the table below, followed by detailed syntax for each method. (API methods can have a shorthand alias name which can be used in the syntax instead of the name)

| Method                     | Description                                                                                     |
|----------------------------|-------------------------------------------------------------------------------------------------|
| <a href="#">onInstance</a> | Perform the operation across all versions of a specific resource (by ID and type) on the server |
| <a href="#">onServer</a>   | Perform the operation across all versions of all resources of all types on the server           |
| <a href="#">onType</a>     | Perform the operation across all versions of all resources of the given type on the server      |

### 36.6.4.1. Method onInstance

Signatures:

- `org.hl7.fhir.instance.model.api.IBaseBundle onInstance(org.hl7.fhir.instance.model.api.IIdType id, Class<org.hl7.fhir.instance.model.api.IBaseBundle> returnType, Integer count, java.util.Date cutoff, org.hl7.fhir.instance.model.api.IPrimitiveType<java.util.Date> iCutoff, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`

The `fhir/onInstance` API method has the parameters listed in the table below:

| Parameter              | Description                                                                                                                                                            | Type           |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|
| <b>count</b>           | Request that the server return only up to theCount number of resources, may be NULL                                                                                    | Integer        |
| <b>cutoff</b>          | Request that the server return only resource versions that were created at or after the given time (inclusive), may be NULL                                            | Date           |
| <b>extraParameters</b> | See ExtraParameters for a full list of parameters that can be passed, may be NULL                                                                                      | Map            |
| <b>iCutoff</b>         | Request that the server return only resource versions that were created at or after the given time (inclusive), may be NULL                                            | IPrimitiveType |
| <b>id</b>              | The IIdType which must be populated with both a resource type and a resource ID at                                                                                     | IIdType        |
| <b>returnType</b>      | Request that the method return a Bundle resource (such as <code>ca.uhn.fhir.model.dstu2.resource.Bundle</code> ). Use this method if you are accessing a DSTU2 server. | Class          |

### 36.6.4.2. Method onServer

Signatures:

- `org.hl7.fhir.instance.model.api.IBaseBundle`

```
onServer(Class<org.hl7.fhir.instance.model.api.IBaseBundle> returnType, Integer count,
java.util.Date cutoff, org.hl7.fhir.instance.model.api.IPrimitiveType<java.util.Date> iCutoff,
java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);
```

The `fhir/onServer` API method has the parameters listed in the table below:

| Parameter              | Description                                                                                                                                                            | Type           |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|
| <b>count</b>           | Request that the server return only up to theCount number of resources, may be NULL                                                                                    | Integer        |
| <b>cutoff</b>          | Request that the server return only resource versions that were created at or after the given time (inclusive), may be NULL                                            | Date           |
| <b>extraParameters</b> | See ExtraParameters for a full list of parameters that can be passed, may be NULL                                                                                      | Map            |
| <b>iCutoff</b>         | Request that the server return only resource versions that were created at or after the given time (inclusive), may be NULL                                            | IPrimitiveType |
| <b>returnType</b>      | Request that the method return a Bundle resource (such as <code>ca.uhn.fhir.model.dstu2.resource.Bundle</code> ). Use this method if you are accessing a DSTU2 server. | Class          |

### 36.6.4.3. Method onType

Signatures:

- `org.hl7.fhir.instance.model.api.IBaseBundle`  
`onType(Class<org.hl7.fhir.instance.model.api.IBaseResource> resourceType, Class<org.hl7.fhir.instance.model.api.IBaseBundle> returnType, Integer count, java.util.Date cutoff, org.hl7.fhir.instance.model.api.IPrimitiveType<java.util.Date> iCutoff, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`

The `fhir/onType` API method has the parameters listed in the table below:

| Parameter              | Description                                                                                                                 | Type    |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------|---------|
| <b>count</b>           | Request that the server return only up to theCount number of resources, may be NULL                                         | Integer |
| <b>cutoff</b>          | Request that the server return only resource versions that were created at or after the given time (inclusive), may be NULL | Date    |
| <b>extraParameters</b> | See ExtraParameters for a full list of parameters that can be passed, may be NULL                                           | Map     |

| Parameter           | Description                                                                                                                                                            | Type           |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|
| <b>iCutoff</b>      | Request that the server return only resource versions that were created at or after the given time (inclusive), may be NULL                                            | IPrimitiveType |
| <b>resourceType</b> | The resource type to search for                                                                                                                                        | Class          |
| <b>returnType</b>   | Request that the method return a Bundle resource (such as <code>ca.uhn.fhir.model.dstu2.resource.Bundle</code> ). Use this method if you are accessing a DSTU2 server. | Class          |

In addition to the parameters above, the fhir API can also use any of the [Query Parameters](#).

Any of the parameters can be provided in either the endpoint URI, or dynamically in a message header. The message header name must be of the format **CamelFhir.parameter**. The **inBody** parameter overrides message header, i.e. the endpoint parameter **inBody=myParameterNameHere** would override a **CamelFhir.myParameterNameHere** header.

### 36.6.5. API: load-page

**Both producer and consumer are supported**

The load-page API is defined in the syntax as follows:

```
fhir:load-page/methodName?[parameters]
```

The 3 method(s) is listed in the table below, followed by detailed syntax for each method. (API methods can have a shorthand alias name which can be used in the syntax instead of the name)

| Method                   | Description                                                                               |
|--------------------------|-------------------------------------------------------------------------------------------|
| <a href="#">byUrl</a>    | Load a page of results using the given URL and bundle type and return a DSTU1 Atom bundle |
| <a href="#">next</a>     | Load the next page of results using the link with relation next in the bundle             |
| <a href="#">previous</a> | Load the previous page of results using the link with relation prev in the bundle         |

#### 36.6.5.1. Method byUrl

Signatures:

- `org.hl7.fhir.instance.model.api.IBaseBundle byUrl(String url, Class<org.hl7.fhir.instance.model.api.IBaseBundle> returnType, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`

The `fhir/byUrl` API method has the parameters listed in the table below:

| Parameter                    | Description                                                                                    | Type   |
|------------------------------|------------------------------------------------------------------------------------------------|--------|
| <code>extraParameters</code> | See <code>ExtraParameters</code> for a full list of parameters that can be passed, may be NULL | Map    |
| <code>returnType</code>      | The return type                                                                                | Class  |
| <code>url</code>             | The search url                                                                                 | String |

### 36.6.5.2. Method next

Signatures:

- `org.hl7.fhir.instance.model.api.IBaseBundle next(org.hl7.fhir.instance.model.api.IBaseBundle bundle, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`

The `fhir/next` API method has the parameters listed in the table below:

| Parameter                    | Description                                                                                    | Type                     |
|------------------------------|------------------------------------------------------------------------------------------------|--------------------------|
| <code>bundle</code>          | The <code>IBaseBundle</code>                                                                   | <code>IBaseBundle</code> |
| <code>extraParameters</code> | See <code>ExtraParameters</code> for a full list of parameters that can be passed, may be NULL | Map                      |

### 36.6.5.3. Method previous

Signatures:

- `org.hl7.fhir.instance.model.api.IBaseBundle previous(org.hl7.fhir.instance.model.api.IBaseBundle bundle, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`

The `fhir/previous` API method has the parameters listed in the table below:

| Parameter                    | Description                                                                                    | Type                     |
|------------------------------|------------------------------------------------------------------------------------------------|--------------------------|
| <code>bundle</code>          | The <code>IBaseBundle</code>                                                                   | <code>IBaseBundle</code> |
| <code>extraParameters</code> | See <code>ExtraParameters</code> for a full list of parameters that can be passed, may be NULL | Map                      |

In addition to the parameters above, the `fhir` API can also use any of the [Query Parameters](#).

Any of the parameters can be provided in either the endpoint URI, or dynamically in a message header. The message header name must be of the format **CamelFhir.parameter**. The **inBody** parameter

overrides message header, i.e. the endpoint parameter **inBody=myParameterNameHere** would override a **CamelFhir.myParameterNameHere** header.

### 36.6.6. API: meta

#### Both producer and consumer are supported

The meta API is defined in the syntax as follows:

```
fhir:meta/methodName?[parameters]
```

The 5 method(s) is listed in the table below, followed by detailed syntax for each method. (API methods can have a shorthand alias name which can be used in the syntax instead of the name)

| Method                          | Description                                                                            |
|---------------------------------|----------------------------------------------------------------------------------------|
| <a href="#">add</a>             | Add the elements in the given metadata to the already existing set (do not remove any) |
| <a href="#">delete</a>          | Delete the elements in the given metadata from the given id                            |
| <a href="#">getFromResource</a> | Fetch the current metadata from a specific resource                                    |
| <a href="#">getFromServer</a>   | Fetch the current metadata from the whole Server                                       |
| <a href="#">getFromType</a>     | Fetch the current metadata from a specific type                                        |

#### 36.6.6.1. Method add

Signatures:

- ```
org.hl7.fhir.instance.model.api.IBaseMetaType
add(org.hl7.fhir.instance.model.api.IBaseMetaType meta, org.hl7.fhir.instance.model.api.IIdType
id, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object>
extraParameters);
```

The fhir/add API method has the parameters listed in the table below:

Parameter	Description	Type
extraParameters	See ExtraParameters for a full list of parameters that can be passed, may be NULL	Map
id	The id	IIdType
meta	The IBaseMetaType class	IBaseMetaType

36.6.6.2. Method delete

Signatures:

- `org.hl7.fhir.instance.model.api.IBaseMetaType`
`delete(org.hl7.fhir.instance.model.api.IBaseMetaType meta,`
`org.hl7.fhir.instance.model.api.IIdType id,`
`java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`

The fhir/delete API method has the parameters listed in the table below:

Parameter	Description	Type
extraParameters	See ExtraParameters for a full list of parameters that can be passed, may be NULL	Map
id	The id	IIdType
meta	The IBaseMetaType class	IBaseMetaType

36.6.6.3. Method getFromResource

Signatures:

- `org.hl7.fhir.instance.model.api.IBaseMetaType`
`getFromResource(Class<org.hl7.fhir.instance.model.api.IBaseMetaType> metaType,`
`org.hl7.fhir.instance.model.api.IIdType id,`
`java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`

The fhir/getFromResource API method has the parameters listed in the table below:

Parameter	Description	Type
extraParameters	See ExtraParameters for a full list of parameters that can be passed, may be NULL	Map
id	The id	IIdType
metaType	The IBaseMetaType class	Class

36.6.6.4. Method getFromServer

Signatures:

- `org.hl7.fhir.instance.model.api.IBaseMetaType`
`getFromServer(Class<org.hl7.fhir.instance.model.api.IBaseMetaType> metaType,`
`java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`

The fhir/getFromServer API method has the parameters listed in the table below:

Parameter	Description	Type
extraParameters	See ExtraParameters for a full list of parameters that can be passed, may be NULL	Map
metaType	The type of the meta datatype for the given FHIR model version (should be MetaDt.class or MetaType.class)	Class

36.6.6.5. Method getFromType

Signatures:

- `org.hl7.fhir.instance.model.api.IBaseMetaType
getFromType(Class<org.hl7.fhir.instance.model.api.IBaseMetaType> metaType, String
resourceType, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object>
extraParameters);`

The `fhir/getFromType` API method has the parameters listed in the table below:

Parameter	Description	Type
extraParameters	See ExtraParameters for a full list of parameters that can be passed, may be NULL	Map
metaType	The IBaseMetaType class	Class
resourceType	The resource type e.g Patient	String

In addition to the parameters above, the `fhir` API can also use any of the [Query Parameters](#).

Any of the parameters can be provided in either the endpoint URI, or dynamically in a message header. The message header name must be of the format **CamelFhir.parameter**. The **inBody** parameter overrides message header, i.e. the endpoint parameter **inBody=myParameterNameHere** would override a **CamelFhir.myParameterNameHere** header.

36.6.7. API: operation

Both producer and consumer are supported

The operation API is defined in the syntax as follows:

```
fhir:operation/methodName?[parameters]
```

The 5 method(s) is listed in the table below, followed by detailed syntax for each method. (API methods can have a shorthand alias name which can be used in the syntax instead of the name)

Method	Description
onInstance	Perform the operation across all versions of a specific resource (by ID and type) on the server
onInstanceVersion	This operation operates on a specific version of a resource
onServer	Perform the operation across all versions of all resources of all types on the server
onType	Perform the operation across all versions of all resources of the given type on the server
processMessage	This operation is called \$process-message as defined by the FHIR specification

36.6.7.1. Method onInstance

Signatures:

- `org.hl7.fhir.instance.model.api.IBaseResource onInstance(org.hl7.fhir.instance.model.api.IIdType id, String name, org.hl7.fhir.instance.model.api.IBaseParameters parameters, Class<org.hl7.fhir.instance.model.api.IBaseParameters> outputParameterType, boolean useHttpGet, Class<org.hl7.fhir.instance.model.api.IBaseResource> returnType, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`

The `fhir/onInstance` API method has the parameters listed in the table below:

Parameter	Description	Type
extraParameters	See <code>ExtraParameters</code> for a full list of parameters that can be passed, may be NULL	Map
id	Resource (version will be stripped)	IIdType
name	Operation name	String
outputParameterType	The type to use for the output parameters (this should be set to <code>Parameters.class</code> drawn from the version of the FHIR structures you are using), may be NULL	Class
parameters	The parameters to use as input. May also be null if the operation does not require any input parameters.	IBaseParameters

Parameter	Description	Type
returnType	If this operation returns a single resource body as its return type instead of a Parameters resource, use this method to specify that resource type. This is useful for certain operations (e.g. Patient/NNN/\$everything) which return a bundle instead of a Parameters resource, may be NULL	Class
useHttpGet	Use HTTP GET verb	Boolean

36.6.7.2. Method onInstanceVersion

Signatures:

- `org.hl7.fhir.instance.model.api.IBaseResource
onInstanceVersion(org.hl7.fhir.instance.model.api.IIdType id, String name,
org.hl7.fhir.instance.model.api.IBaseParameters parameters,
Class<org.hl7.fhir.instance.model.api.IBaseParameters> outputParameterType, boolean
useHttpGet, Class<org.hl7.fhir.instance.model.api.IBaseResource> returnType,
java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`

The fhir/onInstanceVersion API method has the parameters listed in the table below:

Parameter	Description	Type
extraParameters	See ExtraParameters for a full list of parameters that can be passed, may be NULL	Map
id	Resource version	IIdType
name	Operation name	String
outputParameterType	The type to use for the output parameters (this should be set to Parameters.class drawn from the version of the FHIR structures you are using), may be NULL	Class
parameters	The parameters to use as input. May also be null if the operation does not require any input parameters.	IBaseParameters
returnType	If this operation returns a single resource body as its return type instead of a Parameters resource, use this method to specify that resource type. This is useful for certain operations (e.g. Patient/NNN/\$everything) which return a bundle instead of a Parameters resource, may be NULL	Class
useHttpGet	Use HTTP GET verb	Boolean

36.6.7.3. Method onServer

Signatures:

- `org.hl7.fhir.instance.model.api.IBaseResource onServer(String name, org.hl7.fhir.instance.model.api.IBaseParameters parameters, Class<org.hl7.fhir.instance.model.api.IBaseParameters> outputParameterType, boolean useHttpGet, Class<org.hl7.fhir.instance.model.api.IBaseResource> returnType, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`

The fhir/onServer API method has the parameters listed in the table below:

Parameter	Description	Type
extraParameters	See ExtraParameters for a full list of parameters that can be passed, may be NULL	Map
name	Operation name	String
outputParameterType	The type to use for the output parameters (this should be set to Parameters.class drawn from the version of the FHIR structures you are using), may be NULL	Class
parameters	The parameters to use as input. May also be null if the operation does not require any input parameters.	IBaseParameters
returnType	If this operation returns a single resource body as its return type instead of a Parameters resource, use this method to specify that resource type. This is useful for certain operations (e.g. Patient/NNN/\$everything) which return a bundle instead of a Parameters resource, may be NULL	Class
useHttpGet	Use HTTP GET verb	Boolean

36.6.7.4. Method onType

Signatures:

- `org.hl7.fhir.instance.model.api.IBaseResource onType(Class<org.hl7.fhir.instance.model.api.IBaseResource> resourceType, String name, org.hl7.fhir.instance.model.api.IBaseParameters parameters, Class<org.hl7.fhir.instance.model.api.IBaseParameters> outputParameterType, boolean useHttpGet, Class<org.hl7.fhir.instance.model.api.IBaseResource> returnType, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`

The fhir/onType API method has the parameters listed in the table below:

Parameter	Description	Type
extraParameters	See ExtraParameters for a full list of parameters that can be passed, may be NULL	Map
name	Operation name	String
outputParameterType	The type to use for the output parameters (this should be set to Parameters.class drawn from the version of the FHIR structures you are using), may be NULL	Class
parameters	The parameters to use as input. May also be null if the operation does not require any input parameters.	IBaseParameters
resourceType	The resource type to operate on	Class
returnType	If this operation returns a single resource body as its return type instead of a Parameters resource, use this method to specify that resource type. This is useful for certain operations (e.g. Patient/NNN/\$everything) which return a bundle instead of a Parameters resource, may be NULL	Class
useHttpGet	Use HTTP GET verb	Boolean

36.6.7.5. Method processMessage

Signatures:

- `org.hl7.fhir.instance.model.api.IBaseBundle processMessage(String respondToUri, org.hl7.fhir.instance.model.api.IBaseBundle msgBundle, boolean asynchronous, Class<org.hl7.fhir.instance.model.api.IBaseBundle> responseClass, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`

The `fhir/processMessage` API method has the parameters listed in the table below:

Parameter	Description	Type
asynchronous	Whether to process the message asynchronously or synchronously, defaults to synchronous.	Boolean
extraParameters	See ExtraParameters for a full list of parameters that can be passed, may be NULL	Map
msgBundle	Set the Message Bundle to POST to the messaging server	IBaseBundle

Parameter	Description	Type
respondToUri	An optional query parameter indicating that responses from the receiving server should be sent to this URI, may be NULL	String
responseClass	The response class	Class

In addition to the parameters above, the fhir API can also use any of the [Query Parameters](#).

Any of the parameters can be provided in either the endpoint URI, or dynamically in a message header. The message header name must be of the format **CamelFhir.parameter**. The **inBody** parameter overrides message header, i.e. the endpoint parameter **inBody=myParameterNameHere** would override a **CamelFhir.myParameterNameHere** header.

36.6.8. API: patch

Both producer and consumer are supported

The patch API is defined in the syntax as follows:

```
fhir:patch/methodName?[parameters]
```

The 2 method(s) is listed in the table below, followed by detailed syntax for each method. (API methods can have a shorthand alias name which can be used in the syntax instead of the name)

Method	Description
patchById	Applies the patch to the given resource ID
patchByUrl	Specifies that the update should be performed as a conditional create against a given search URL

36.6.8.1. Method patchById

Signatures:

- `ca.uhn.fhir.rest.api.MethodOutcome patchById(String patchBody, String stringId, ca.uhn.fhir.rest.api.PreferReturnEnum preferReturn, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`
- `ca.uhn.fhir.rest.api.MethodOutcome patchById(String patchBody, org.hl7.fhir.instance.model.api.IIdType id, ca.uhn.fhir.rest.api.PreferReturnEnum preferReturn, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`

The fhir/patchById API method has the parameters listed in the table below:

Parameter	Description	Type
extraParameters	See ExtraParameters for a full list of parameters that can be passed, may be NULL	Map
id	The resource ID to patch	IdType
patchBody	The body of the patch document serialized in either XML or JSON which conforms to	String
preferReturn	Add a Prefer header to the request, which requests that the server include or suppress the resource body as a part of the result. If a resource is returned by the server it will be parsed and accessible to the client via <code>MethodOutcome#getResource()</code>	PreferReturnEnum
stringId	The resource ID to patch	String

36.6.8.2. Method patchByUrl

Signatures:

- `ca.uhn.fhir.rest.api.MethodOutcome patchByUrl(String patchBody, String url, ca.uhn.fhir.rest.api.PreferReturnEnum preferReturn, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`

The `fhir/patchByUrl` API method has the parameters listed in the table below:

Parameter	Description	Type
extraParameters	See ExtraParameters for a full list of parameters that can be passed, may be NULL	Map
patchBody	The body of the patch document serialized in either XML or JSON which conforms to	String
preferReturn	Add a Prefer header to the request, which requests that the server include or suppress the resource body as a part of the result. If a resource is returned by the server it will be parsed and accessible to the client via <code>MethodOutcome#getResource()</code>	PreferReturnEnum
url	The search URL to use. The format of this URL should be of the form <code>ResourceTypeParameters</code> , for example: <code>Patientname=Smith&identifier=13.2.4.11.4%7C847366</code>	String

In addition to the parameters above, the `fhir` API can also use any of the [Query Parameters](#).

Any of the parameters can be provided in either the endpoint URI, or dynamically in a message header. The message header name must be of the format **CamelFhir.parameter**. The **inBody** parameter overrides message header, i.e. the endpoint parameter **inBody=myParameterNameHere** would override a **CamelFhir.myParameterNameHere** header.

36.6.9. API: read

Both producer and consumer are supported

The read API is defined in the syntax as follows:

```
fhir:read/methodName?[parameters]
```

The 2 method(s) is listed in the table below, followed by detailed syntax for each method. (API methods can have a shorthand alias name which can be used in the syntax instead of the name)

Method	Description
resourceById	Reads a IBaseResource on the server by id
resourceByUrl	Reads a IBaseResource on the server by url

36.6.9.1. Method resourceById

Signatures:

- `org.hl7.fhir.instance.model.api.IBaseResource resourceById(Class<org.hl7.fhir.instance.model.api.IBaseResource> resource, Long longId, String ifVersionMatches, Boolean returnNull, org.hl7.fhir.instance.model.api.IBaseResource returnResource, Boolean throwError, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`
- `org.hl7.fhir.instance.model.api.IBaseResource resourceById(Class<org.hl7.fhir.instance.model.api.IBaseResource> resource, String stringId, String version, String ifVersionMatches, Boolean returnNull, org.hl7.fhir.instance.model.api.IBaseResource returnResource, Boolean throwError, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`
- `org.hl7.fhir.instance.model.api.IBaseResource resourceById(Class<org.hl7.fhir.instance.model.api.IBaseResource> resource, org.hl7.fhir.instance.model.api.IIdType id, String ifVersionMatches, Boolean returnNull, org.hl7.fhir.instance.model.api.IBaseResource returnResource, Boolean throwError, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`
- `org.hl7.fhir.instance.model.api.IBaseResource resourceById(String resourceClass, Long longId, String ifVersionMatches, Boolean returnNull, org.hl7.fhir.instance.model.api.IBaseResource returnResource, Boolean throwError, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`
- `org.hl7.fhir.instance.model.api.IBaseResource resourceById(String resourceClass, String stringId, String ifVersionMatches, String version, Boolean returnNull, org.hl7.fhir.instance.model.api.IBaseResource returnResource, Boolean throwError, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`

- `org.hl7.fhir.instance.model.api.IBaseResource resourceById(String resourceClass, org.hl7.fhir.instance.model.api.IIdType id, String ifVersionMatches, Boolean returnNull, org.hl7.fhir.instance.model.api.IBaseResource returnResource, Boolean throwError, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`

The `fhir/resourceById` API method has the parameters listed in the table below:

Parameter	Description	Type
extraParameters	See <code>ExtraParameters</code> for a full list of parameters that can be passed, may be <code>NULL</code>	Map
id	The <code>IIdType</code> referencing the resource	<code>IIdType</code>
ifVersionMatches	A version to match against the newest version on the server	String
longId	The resource ID	Long
resource	The resource to read (e.g. Patient)	Class
resourceClass	The resource to read (e.g. Patient)	String
returnNull	Return null if version matches	Boolean
returnResource	Return the resource if version matches	<code>IBaseResource</code>
stringId	The resource ID	String
throwError	Throw error if the version matches	Boolean
version	The resource version	String

36.6.9.2. Method `resourceByUrl`

Signatures:

- `org.hl7.fhir.instance.model.api.IBaseResource resourceByUrl(Class<org.hl7.fhir.instance.model.api.IBaseResource> resource, String url, String ifVersionMatches, Boolean returnNull, org.hl7.fhir.instance.model.api.IBaseResource returnResource, Boolean throwError, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`
- `org.hl7.fhir.instance.model.api.IBaseResource resourceByUrl(Class<org.hl7.fhir.instance.model.api.IBaseResource> resource, org.hl7.fhir.instance.model.api.IIdType iUrl, String ifVersionMatches, Boolean returnNull, org.hl7.fhir.instance.model.api.IBaseResource returnResource, Boolean throwError, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`
- `org.hl7.fhir.instance.model.api.IBaseResource resourceByUrl(String resourceClass, String url, String ifVersionMatches, Boolean returnNull, org.hl7.fhir.instance.model.api.IBaseResource`

```
returnResource, Boolean throwError,
java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);
```

- `org.hl7.fhir.instance.model.api.IBaseResource resourceByUrl(String resourceClass, org.hl7.fhir.instance.model.api.IIdType iUrl, String ifVersionMatches, Boolean returnNull, org.hl7.fhir.instance.model.api.IBaseResource returnResource, Boolean throwError, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`

The `fhir/resourceByUrl` API method has the parameters listed in the table below:

Parameter	Description	Type
extraParameters	See <code>ExtraParameters</code> for a full list of parameters that can be passed, may be <code>NULL</code>	Map
iUrl	The <code>IIdType</code> referencing the resource by absolute url	<code>IIdType</code>
ifVersionMatches	A version to match against the newest version on the server	String
resource	The resource to read (e.g. Patient)	Class
resourceClass	The resource to read (e.g. Patient.class)	String
returnNull	Return null if version matches	Boolean
returnResource	Return the resource if version matches	<code>IBaseResource</code>
throwError	Throw error if the version matches	Boolean
url	Referencing the resource by absolute url	String

In addition to the parameters above, the `fhir` API can also use any of the [Query Parameters](#).

Any of the parameters can be provided in either the endpoint URI, or dynamically in a message header. The message header name must be of the format **CamelFhir.parameter**. The **inBody** parameter overrides message header, i.e. the endpoint parameter **inBody=myParameterNameHere** would override a **CamelFhir.myParameterNameHere** header.

36.6.10. API: search

Both producer and consumer are supported

The search API is defined in the syntax as follows:

```
fhir:search/methodName?[parameters]
```

The 1 method(s) is listed in the table below, followed by detailed syntax for each method. (API methods can have a shorthand alias name which can be used in the syntax instead of the name)

Method	Description
searchByUrl	Perform a search directly by URL

36.6.10.1. Method `searchByUrl`

Signatures:

- `org.hl7.fhir.instance.model.api.IBaseBundle searchByUrl(String url, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`

The `fhir/searchByUrl` API method has the parameters listed in the table below:

Parameter	Description	Type
extraParameters	See <code>ExtraParameters</code> for a full list of parameters that can be passed, may be NULL	Map
url	The URL to search for. Note that this URL may be complete (e.g.) in which case the client's base URL will be ignored. Or it can be relative (e.g. <code>Patientname=foo</code>) in which case the client's base URL will be used.	String

In addition to the parameters above, the `fhir` API can also use any of the [Query Parameters](#).

Any of the parameters can be provided in either the endpoint URI, or dynamically in a message header. The message header name must be of the format **CamelFhir.parameter**. The **inBody** parameter overrides message header, i.e. the endpoint parameter **inBody=myParameterNameHere** would override a **CamelFhir.myParameterNameHere** header.

36.6.11. API: transaction

Both producer and consumer are supported

The transaction API is defined in the syntax as follows:

```
fhir:transaction/methodName?[parameters]
```

The 2 method(s) is listed in the table below, followed by detailed syntax for each method. (API methods can have a shorthand alias name which can be used in the syntax instead of the name)

Method	Description
withBundle	Use the given raw text (should be a Bundle resource) as the transaction input
withResources	Use a list of resources as the transaction input

36.6.11.1. Method withBundle

Signatures:

- `String withBundle(String stringBundle, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`
- `org.hl7.fhir.instance.model.api.IBaseBundle withBundle(org.hl7.fhir.instance.model.api.IBaseBundle bundle, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`

The fhir/withBundle API method has the parameters listed in the table below:

Parameter	Description	Type
bundle	Bundle to use in the transaction	IBaseBundle
extraParameters	See ExtraParameters for a full list of parameters that can be passed, may be NULL	Map
stringBundle	Bundle to use in the transaction	String

36.6.11.2. Method withResources

Signatures:

- `java.util.List<org.hl7.fhir.instance.model.api.IBaseResource> withResources(java.util.List<org.hl7.fhir.instance.model.api.IBaseResource> resources, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`

The fhir/withResources API method has the parameters listed in the table below:

Parameter	Description	Type
extraParameters	See ExtraParameters for a full list of parameters that can be passed, may be NULL	Map
resources	Resources to use in the transaction	List

In addition to the parameters above, the fhir API can also use any of the [Query Parameters](#).

Any of the parameters can be provided in either the endpoint URI, or dynamically in a message header. The message header name must be of the format **CamelFhir.parameter**. The **inBody** parameter overrides message header, i.e. the endpoint parameter **inBody=myParameterNameHere** would override a **CamelFhir.myParameterNameHere** header.

36.6.12. API: update

Both producer and consumer are supported

The update API is defined in the syntax as follows:

fhir:update/methodName?[parameters]

The 2 method(s) is listed in the table below, followed by detailed syntax for each method. (API methods can have a shorthand alias name which can be used in the syntax instead of the name)

Method	Description
resource	Updates a IBaseResource on the server by id
resourceByUrl	Updates a IBaseResource on the server by search url

36.6.12.1. Method resource

Signatures:

- `ca.uhn.fhir.rest.api.MethodOutcome resource(String resourceAsString, String stringId, ca.uhn.fhir.rest.api.PreferReturnEnum preferReturn, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`
- `ca.uhn.fhir.rest.api.MethodOutcome resource(String resourceAsString, org.hl7.fhir.instance.model.api.IIdType id, ca.uhn.fhir.rest.api.PreferReturnEnum preferReturn, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`
- `ca.uhn.fhir.rest.api.MethodOutcome resource(org.hl7.fhir.instance.model.api.IBaseResource resource, String stringId, ca.uhn.fhir.rest.api.PreferReturnEnum preferReturn, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`
- `ca.uhn.fhir.rest.api.MethodOutcome resource(org.hl7.fhir.instance.model.api.IBaseResource resource, org.hl7.fhir.instance.model.api.IIdType id, ca.uhn.fhir.rest.api.PreferReturnEnum preferReturn, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`

The fhir/resource API method has the parameters listed in the table below:

Parameter	Description	Type
extraParameters	See ExtraParameters for a full list of parameters that can be passed, may be NULL	Map
id	The IIdType referencing the resource	IIdType
preferReturn	Whether the server include or suppress the resource body as a part of the result	PreferReturnEnum
resource	The resource to update (e.g. Patient)	IBaseResource
resourceAsString	The resource body to update	String
stringId	The ID referencing the resource	String

36.6.12.2. Method resourceBySearchUrl

Signatures:

- `ca.uhn.fhir.rest.api.MethodOutcome resourceBySearchUrl(String resourceAsString, String url, ca.uhn.fhir.rest.api.PreferReturnEnum preferReturn, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`
- `ca.uhn.fhir.rest.api.MethodOutcome resourceBySearchUrl(org.hl7.fhir.instance.model.api.IBaseResource resource, String url, ca.uhn.fhir.rest.api.PreferReturnEnum preferReturn, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`

The `fhir/resourceBySearchUrl` API method has the parameters listed in the table below:

Parameter	Description	Type
extraParameters	See <code>ExtraParameters</code> for a full list of parameters that can be passed, may be NULL	Map
preferReturn	Whether the server include or suppress the resource body as a part of the result	PreferReturnEnum
resource	The resource to update (e.g. Patient)	IBaseResource
resourceAsString	The resource body to update	String
url	Specifies that the update should be performed as a conditional create against a given search URL	String

In addition to the parameters above, the `fhir` API can also use any of the [Query Parameters](#).

Any of the parameters can be provided in either the endpoint URI, or dynamically in a message header. The message header name must be of the format **CamelFhir.parameter**. The **inBody** parameter overrides message header, i.e. the endpoint parameter **inBody=myParameterNameHere** would override a **CamelFhir.myParameterNameHere** header.

36.6.13. API: validate

Both producer and consumer are supported

The `validate` API is defined in the syntax as follows:

```
fhir:validate/methodName?[parameters]
```

The 1 method(s) is listed in the table below, followed by detailed syntax for each method. (API methods can have a shorthand alias name which can be used in the syntax instead of the name)

Method	Description
resource	Validates the resource

36.6.13.1. Method resource

Signatures:

- `ca.uhn.fhir.rest.api.MethodOutcome resource(String resourceAsString, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`
- `ca.uhn.fhir.rest.api.MethodOutcome resource(org.hl7.fhir.instance.model.api.IBaseResource resource, java.util.Map<org.apache.camel.component.fhir.api.ExtraParameters, Object> extraParameters);`

The `fhir/resource` API method has the parameters listed in the table below:

Parameter	Description	Type
extraParameters	See <code>ExtraParameters</code> for a full list of parameters that can be passed, may be NULL	Map
resource	The <code>IBaseResource</code> to validate	<code>IBaseResource</code>
resourceAsString	Raw resource to validate	String

In addition to the parameters above, the `fhir` API can also use any of the [Query Parameters](#).

Any of the parameters can be provided in either the endpoint URI, or dynamically in a message header. The message header name must be of the format **CamelFhir.parameter**. The **inBody** parameter overrides message header, i.e. the endpoint parameter **inBody=myParameterNameHere** would override a **CamelFhir.myParameterNameHere** header.

36.7. SPRING BOOT AUTO-CONFIGURATION

The component supports 56 options, which are listed below.

Name	Description	Default	Type
camel.component.fhir.access-token	OAuth access token.		String
camel.component.fhir.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.fhir.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.fhir.client	To use the custom client. The option is a <code>ca.uhn.fhir.rest.client.api.IGenericClient</code> type.		IGenericClient
camel.component.fhir.client-factory	To use the custom client factory. The option is a <code>ca.uhn.fhir.rest.client.api.IRestfulClientFactory</code> type.		IRestfulClientFactory
camel.component.fhir.compress	Compresses outgoing (POST/PUT) contents to the GZIP format.	false	Boolean
camel.component.fhir.configuration	To use the shared configuration. The option is a <code>org.apache.camel.component.fhir.FhirConfiguration</code> type.		FhirConfiguration
camel.component.fhir.connection-timeout	How long to try and establish the initial TCP connection (in ms).	10000	Integer
camel.component.fhir.defer-model-scanning	When this option is set, model classes will not be scanned for children until the child list for the given type is actually accessed.	false	Boolean
camel.component.fhir.enabled	Whether to enable auto configuration of the fhir component. This is enabled by default.		Boolean
camel.component.fhir.encoding	Encoding to use for all request.		String
camel.component.fhir.fhir-context	FhirContext is an expensive object to create. To avoid creating multiple instances, it can be set directly. The option is a <code>ca.uhn.fhir.context.FhirContext</code> type.		FhirContext
camel.component.fhir.fhir-version	The FHIR Version to use.	R4	String

Name	Description	Default	Type
<code>camel.component.fhir.force-conformance-check</code>	Force conformance check.	false	Boolean
<code>camel.component.fhir.lazy-start-producer</code>	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
<code>camel.component.fhir.log</code>	Will log every requests and responses.	false	Boolean
<code>camel.component.fhir.password</code>	Username to use for basic authentication.		String
<code>camel.component.fhir.pretty-print</code>	Pretty print all request.	false	Boolean
<code>camel.component.fhir.proxy-host</code>	The proxy host.		String
<code>camel.component.fhir.proxy-password</code>	The proxy password.		String
<code>camel.component.fhir.proxy-port</code>	The proxy port.		Integer
<code>camel.component.fhir.proxy-user</code>	The proxy username.		String
<code>camel.component.fhir.server-url</code>	The FHIR server base URL.		String
<code>camel.component.fhir.session-cookie</code>	HTTP session cookie to add to every request.		String

Name	Description	Default	Type
camel.component.fhir.socket-timeout	How long to block for individual read/write operations (in ms).	10000	Integer
camel.component.fhir.summary	Request that the server modify the response using the <code>_summary</code> param.		String
camel.component.fhir.username	Username to use for basic authentication.		String
camel.component.fhir.validation-mode	When should Camel validate the FHIR Server's conformance statement.	ONCE	String
camel.dataformat.fhirjson.content-type-header	Whether the data format should set the Content-Type header with the type from the data format. For example <code>application/xml</code> for data formats marshalling to XML, or <code>application/json</code> for data formats marshalling to JSON.	true	Boolean
camel.dataformat.fhirjson.dont-encode-elements	If provided, specifies the elements which should NOT be encoded. Valid values for this field would include: Patient - Don't encode patient and all its children Patient.name - Don't encode the patient's name Patient.name.family - Don't encode the patient's family name .text - Don't encode the text element on any resource (only the very first position may contain a wildcard) DSTU2 note: Note that values including meta, such as <code>Patient.meta</code> will work for DSTU2 parsers, but values with subelements on meta such as <code>Patient.meta.lastUpdated</code> will only work in DSTU3 mode.		Set
camel.dataformat.fhirjson.dont-strip-versions-from-references-at-paths	If supplied value(s), any resource references at the specified paths will have their resource versions encoded instead of being automatically stripped during the encoding process. This setting has no effect on the parsing process. This method provides a finer-grained level of control than <code>setStripVersionsFromReferences(String)</code> and any paths specified by this method will be encoded even if <code>setStripVersionsFromReferences(String)</code> has been set to true (which is the default).		List
camel.dataformat.fhirjson.enabled	Whether to enable auto configuration of the <code>fhirJson</code> data format. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.dataformat.fhirjson.encode-elements	If provided, specifies the elements which should be encoded, to the exclusion of all others. Valid values for this field would include: Patient - Encode patient and all its children Patient.name - Encode only the patient's name Patient.name.family - Encode only the patient's family name .text - Encode the text element on any resource (only the very first position may contain a wildcard) .(mandatory) - This is a special case which causes any mandatory fields (min 0) to be encoded.		Set
camel.dataformat.fhirjson.encode-elements-applies-to-child-resources-only	If set to true (default is false), the values supplied to setEncodeElements(Set) will not be applied to the root resource (typically a Bundle), but will be applied to any sub-resources contained within it (i.e. search result resources in that bundle).	false	Boolean
camel.dataformat.fhirjson.fhir-version	The version of FHIR to use. Possible values are: DSTU2,DSTU2_HL7ORG,DSTU2_1,DSTU3,R4.	DSTU3	String
camel.dataformat.fhirjson.omit-resource-id	If set to true (default is false) the ID of any resources being encoded will not be included in the output. Note that this does not apply to contained resources, only to root resources. In other words, if this is set to true, contained resources will still have local IDs but the outer/containing ID will not have an ID.	false	Boolean
camel.dataformat.fhirjson.override-resource-id-with-bundle-entry-full-url	If set to true (which is the default), the Bundle.entry.fullUrl will override the Bundle.entry.resource's resource id if the fullUrl is defined. This behavior happens when parsing the source data into a Bundle object. Set this to false if this is not the desired behavior (e.g. the client code wishes to perform additional validation checks between the fullUrl and the resource id).	false	Boolean
camel.dataformat.fhirjson.pretty-print	Sets the pretty print flag, meaning that the parser will encode resources with human-readable spacing and newlines between elements instead of condensing output as much as possible.	false	Boolean
camel.dataformat.fhirjson.server-base-url	Sets the server's base URL used by this parser. If a value is set, resource references will be turned into relative references if they are provided as absolute URLs but have a base matching the given base.		String

Name	Description	Default	Type
camel.dataformat.fhirjson.strip-versions-from-references	If set to true (which is the default), resource references containing a version will have the version removed when the resource is encoded. This is generally good behaviour because in most situations, references from one resource to another should be to the resource by ID, not by ID and version. In some cases though, it may be desirable to preserve the version in resource links. In that case, this value should be set to false. This method provides the ability to globally disable reference encoding. If finer-grained control is needed, use <code>setDontStripVersionsFromReferencesAtPath(List)</code> .	false	Boolean
camel.dataformat.fhirjson.summary-mode	If set to true (default is false) only elements marked by the FHIR specification as being summary elements will be included.	false	Boolean
camel.dataformat.fhirjson.suppress-narratives	If set to true (default is false), narratives will not be included in the encoded values.	false	Boolean
camel.dataformat.fhirxml.content-type-header	Whether the data format should set the Content-Type header with the type from the data format. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON.	true	Boolean
camel.dataformat.fhirxml.dont-encode-elements	If provided, specifies the elements which should NOT be encoded. Valid values for this field would include: Patient - Don't encode patient and all its children Patient.name - Don't encode the patient's name Patient.name.family - Don't encode the patient's family name .text - Don't encode the text element on any resource (only the very first position may contain a wildcard) DSTU2 note: Note that values including meta, such as Patient.meta will work for DSTU2 parsers, but values with subelements on meta such as Patient.meta.lastUpdated will only work in DSTU3 mode.		Set

Name	Description	Default	Type
<code>camel.dataformat.fhirxml.dont-strip-versions-from-references-at-paths</code>	If supplied value(s), any resource references at the specified paths will have their resource versions encoded instead of being automatically stripped during the encoding process. This setting has no effect on the parsing process. This method provides a finer-grained level of control than <code>setStripVersionsFromReferences(String)</code> and any paths specified by this method will be encoded even if <code>setStripVersionsFromReferences(String)</code> has been set to true (which is the default).		List
<code>camel.dataformat.fhirxml.enabled</code>	Whether to enable auto configuration of the fhirXml data format. This is enabled by default.		Boolean
<code>camel.dataformat.fhirxml.encode-elements</code>	If provided, specifies the elements which should be encoded, to the exclusion of all others. Valid values for this field would include: Patient - Encode patient and all its children Patient.name - Encode only the patient's name Patient.name.family - Encode only the patient's family name .text - Encode the text element on any resource (only the very first position may contain a wildcard) .(mandatory) - This is a special case which causes any mandatory fields (min 0) to be encoded.		Set
<code>camel.dataformat.fhirxml.encode-elements-applies-to-child-resources-only</code>	If set to true (default is false), the values supplied to <code>setEncodeElements(Set)</code> will not be applied to the root resource (typically a Bundle), but will be applied to any sub-resources contained within it (i.e. search result resources in that bundle).	false	Boolean
<code>camel.dataformat.fhirxml.fhir-version</code>	The version of FHIR to use. Possible values are: DSTU2,DSTU2_HL7ORG,DSTU2_1,DSTU3,R4.	DSTU3	String
<code>camel.dataformat.fhirxml.omit-resource-id</code>	If set to true (default is false) the ID of any resources being encoded will not be included in the output. Note that this does not apply to contained resources, only to root resources. In other words, if this is set to true, contained resources will still have local IDs but the outer/containing ID will not have an ID.	false	Boolean

Name	Description	Default	Type
<code>camel.dataformat.fhirxml.override-resource-id-with-bundle-entry-full-url</code>	If set to true (which is the default), the <code>Bundle.entry.fullUrl</code> will override the <code>Bundle.entry.resource</code> 's resource id if the <code>fullUrl</code> is defined. This behavior happens when parsing the source data into a <code>Bundle</code> object. Set this to false if this is not the desired behavior (e.g. the client code wishes to perform additional validation checks between the <code>fullUrl</code> and the resource id).	false	Boolean
<code>camel.dataformat.fhirxml.pretty-print</code>	Sets the pretty print flag, meaning that the parser will encode resources with human-readable spacing and newlines between elements instead of condensing output as much as possible.	false	Boolean
<code>camel.dataformat.fhirxml.server-base-url</code>	Sets the server's base URL used by this parser. If a value is set, resource references will be turned into relative references if they are provided as absolute URLs but have a base matching the given base.		String
<code>camel.dataformat.fhirxml.strip-versions-from-references</code>	If set to true (which is the default), resource references containing a version will have the version removed when the resource is encoded. This is generally good behaviour because in most situations, references from one resource to another should be to the resource by ID, not by ID and version. In some cases though, it may be desirable to preserve the version in resource links. In that case, this value should be set to false. This method provides the ability to globally disable reference encoding. If finer-grained control is needed, use <code>setDontStripVersionsFromReferencesAtPath(List)</code> .	false	Boolean
<code>camel.dataformat.fhirxml.summary-mode</code>	If set to true (default is false) only elements marked by the FHIR specification as being summary elements will be included.	false	Boolean
<code>camel.dataformat.fhirxml.suppress-narratives</code>	If set to true (default is false), narratives will not be included in the encoded values.	false	Boolean

CHAPTER 37. FILE

Both producer and consumer are supported

The File component provides access to file systems, allowing files to be processed by any other Camel Components or messages from other components to be saved to disk.

37.1. DEPENDENCIES

When using **file** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-file-starter</artifactId>
</dependency>
```

37.2. URI FORMAT

```
file:directoryName[?options]
```

Where **directoryName** represents the underlying file directory.

Only directories

Camel supports only endpoints configured with a starting directory. So the **directoryName** must be a directory. If you want to consume a single file only, you can use the **fileName** option, e.g. by setting **fileName=thefilename**. Also, the starting directory must not contain dynamic expressions with **\${ }** placeholders. Again use the **fileName** option to specify the dynamic part of the filename.

NOTE

Avoid reading files currently being written by another application

Beware the JDK File IO API is a bit limited in detecting whether another application is currently writing/copying a file. And the implementation can be different depending on OS platform as well. This could lead to that Camel thinks the file is not locked by another process and start consuming it. Therefore you have to do your own investigation what suits your environment. To help with this Camel provides different **readLock** options and **doneFileName** option that you can use. See also the section [Consuming files from folders where others drop files directly](#).

37.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

37.3.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the

endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).
- directly in the Java code.

37.3.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

37.4. COMPONENT OPTIONS

The File component supports 3 options, which are listed below.

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

37.5. ENDPOINT OPTIONS

The File endpoint is configured using URI syntax:

```
file:directoryName
```

with the following path and query parameters:

37.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
directoryName (common)	Required The starting directory.		File

37.5.2. Query Parameters (94 parameters)

Name	Description	Default	Type
------	-------------	---------	------

Name	Description	Default	Type
charset (common)	This option is used to specify the encoding of the file. You can use this on the consumer, to specify the encodings of the files, which allow Camel to know the charset it should load the file content in case the file content is being accessed. Likewise when writing a file, you can use this option to specify which charset to write the file as well. Do mind that when writing the file Camel may have to read the message content into memory to be able to convert the data into the configured charset, so do not use this if you have big messages.		String
doneFileName (common)	Producer: If provided, then Camel will write a 2nd done file when the original file has been written. The done file will be empty. This option configures what file name to use. Either you can specify a fixed name. Or you can use dynamic placeholders. The done file will always be written in the same folder as the original file. Consumer: If provided, Camel will only consume files if a done file exists. This option configures what file name to use. Either you can specify a fixed name. Or you can use dynamic placeholders. The done file is always expected in the same folder as the original file. Only <code>\$\$\{file.name}</code> and <code>\$\$\{file.name.next}</code> is supported as dynamic placeholders.		String
fileName (common)	Use Expression such as File Language to dynamically set the filename. For consumers, it's used as a filename filter. For producers, it's used to evaluate the filename to write. If an expression is set, it take precedence over the CamelFileName header. (Note: The header itself can also be an Expression). The expression options support both String and Expression types. If the expression is a String type, it is always evaluated using the File Language. If the expression is an Expression type, the specified Expression type is used - this allows you, for instance, to use OGNL expressions. For the consumer, you can use it to filter filenames, so you can for instance consume today's file using the File Language syntax: <code>mydata-\$\$\{date:now:yyyyMMdd}.txt</code> . The producers support the CamelOverrideFileName header which takes precedence over any existing CamelFileName header; the CamelOverrideFileName is a header that is used only once, and makes it easier as this avoids to temporary store CamelFileName and have to restore it afterwards.		String

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
delete (consumer)	If true, the file will be deleted after it is processed successfully.	false	boolean
moveFailed (consumer)	Sets the move failure expression based on Simple language. For example, to move files into a .error subdirectory use: <code>.error</code> . Note: When moving the files to the fail location Camel will handle the error and will not pick up the file again.		String
noop (consumer)	If true, the file is not moved or deleted in any way. This option is good for readonly data, or for ETL type requirements. If <code>noop=true</code> , Camel will set <code>idempotent=true</code> as well, to avoid consuming the same files over and over again.	false	boolean
preMove (consumer)	Expression (such as File Language) used to dynamically set the filename when moving it before processing. For example to move in-progress files into the order directory set this value to <code>order</code> .		String
preSort (consumer)	When pre-sort is enabled then the consumer will sort the file and directory names during polling, that was retrieved from the file system. You may want to do this in case you need to operate on the files in a sorted order. The pre-sort is executed before the consumer starts to filter, and accept files to process by Camel. This option is default=false meaning disabled.	false	boolean
recursive (consumer)	If a directory, will look for files in all the sub-directories as well.	false	boolean
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean
directoryMustExist (consumer (advanced))	Similar to the <code>startingDirectoryMustExist</code> option but this applies during polling (after starting the consumer).	false	boolean

Name	Description	Default	Type
exceptionHandler (consumer (advanced))	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at <code>WARN</code> or <code>ERROR</code> level and ignored.		<code>ExceptionHandler</code>
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • <code>InOnly</code> • <code>InOut</code> • <code>InOptionalOut</code>		<code>ExchangePattern</code>
extendedAttributes (consumer (advanced))	To define which file attributes of interest. Like <code>posix:permissions, posix:owner, basic:lastAccessTime</code> , it supports basic wildcard like <code>posix:*, basic:lastAccessTime</code> .		<code>String</code>
inProgressRepository (consumer (advanced))	A pluggable in-progress repository <code>org.apache.camel.spi.IdempotentRepository</code> . The in-progress repository is used to account the current in progress files being consumed. By default a memory based repository is used.		<code>IdempotentRepository</code>
localWorkDirectory (consumer (advanced))	When consuming, a local work directory can be used to store the remote file content directly in local files, to avoid loading the content into memory. This is beneficial, if you consume a very big remote file and thus can conserve memory.		<code>String</code>
onCompletionExceptionHandler (consumer (advanced))	To use a custom <code>org.apache.camel.spi.ExceptionHandler</code> to handle any thrown exceptions that happens during the file on completion process where the consumer does either a commit or rollback. The default implementation will log any exception at <code>WARN</code> level and ignore.		<code>ExceptionHandler</code>
pollStrategy (consumer (advanced))	A pluggable <code>org.apache.camel.PollingConsumerPollingStrategy</code> allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an <code>Exchange</code> have been created and being routed in Camel.		<code>PollingConsumerPollStrategy</code>

Name	Description	Default	Type
probeContentType (consumer (advanced))	Whether to enable probing of the content type. If enable then the consumer uses <code>Files#probeContentType(java.nio.file.Path)</code> to determine the content-type of the file, and store that as a header with key <code>Exchange#FILE_CONTENT_TYPE</code> on the Message.	false	boolean
processStrategy (consumer (advanced))	A pluggable <code>org.apache.camel.component.file.GenericFileProcessStrategy</code> allowing you to implement your own <code>readLock</code> option or similar. Can also be used when special conditions must be met before a file can be consumed, such as a special ready file exists. If this option is set then the <code>readLock</code> option does not apply.		<code>GenericFileProcessStrategy</code>
resumeStrategy (consumer (advanced))	Set a resume strategy for files. This makes it possible to define a strategy for resuming reading files after the last point before stopping the application. See the <code>FileConsumerResumeStrategy</code> for implementation details.		<code>FileConsumerResumeStrategy</code>
startingDirectoryMustExist (consumer (advanced))	Whether the starting directory must exist. Mind that the <code>autoCreate</code> option is default enabled, which means the starting directory is normally auto created if it doesn't exist. You can disable <code>autoCreate</code> and enable this to ensure the starting directory must exist. Will thrown an exception if the directory doesn't exist.	false	boolean
startingDirectoryMustHaveAccess (consumer (advanced))	Whether the starting directory has access permissions. Mind that the <code>startingDirectoryMustExist</code> parameter must be set to true in order to verify that the directory exists. Will thrown an exception if the directory doesn't have read and write permissions.	false	boolean
appendChars (producer)	Used to append characters (text) after writing files. This can for example be used to add new lines or other separators when writing and appending new files or existing files. To specify new-line (slash-n or slash-r) or tab (slash-t) characters then escape with an extra slash, eg slash-slash-n.		String

Name	Description	Default	Type
fileExist (producer)	What to do if a file already exists with the same name. Override, which is the default, replaces the existing file. - Append - adds content to the existing file. - Fail - throws a <code>GenericFileOperationException</code>, indicating that there is already an existing file. - Ignore - silently ignores the problem and does not override the existing file, but assumes everything is okay. - Move - option requires to use the <code>moveExisting</code> option to be configured as well. The option <code>eagerDeleteTargetFile</code> can be used to control what to do if an moving the file, and there exists already an existing file, otherwise causing the move operation to fail. The Move option will move any existing files, before writing the target file. - TryRename is only applicable if <code>tempFileName</code> option is in use. This allows to try renaming the file from the temporary name to the actual name, without doing any exists check. This check may be faster on some file systems and especially FTP servers. Enum values: ● Override ● Append ● Fail ● Ignore ● Move ● TryRename	Override	GenericFileExist
flatten (producer)	Flatten is used to flatten the file name path to strip any leading paths, so it's just the file name. This allows you to consume recursively into sub-directories, but when you eg write the files to another directory they will be written in a single directory. Setting this to true on the producer enforces that any file name in <code>CamelFileName</code> header will be stripped for any leading paths.	false	boolean
jailStartingDirectory (producer)	Used for jailing (restricting) writing files to the starting directory (and sub) only. This is enabled by default to not allow Camel to write files to outside directories (to be more secured out of the box). You can turn this off to allow writing files to directories outside the starting directory, such as parent or root folders.	true	boolean

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
moveExisting (producer)	Expression (such as File Language) used to compute file name to use when fileExist=Move is configured. To move files into a backup subdirectory just enter backup. This option only supports the following File Language tokens: file:name, file:name.ext, file:name.noext, file:onlyname, file:onlyname.noext, file:ext, and file:parent. Notice the file:parent is not supported by the FTP component, as the FTP component can only move any existing files to a relative directory based on current dir as base.		String
tempFileName (producer)	The same as tempPrefix option but offering a more fine grained control on the naming of the temporary filename as it uses the File Language. The location for tempFileName is relative to the final file location in the option 'fileName', not the target directory in the base uri. For example if option fileName includes a directory prefix: dir/finalFilename then tempFileName is relative to that subdirectory dir.		String
tempPrefix (producer)	This option is used to write the file using a temporary name and then, after the write is complete, rename it to the real name. Can be used to identify files being written and also avoid consumers (not using exclusive read locks) reading in progress files. Is often used by FTP when uploading big files.		String
allowNullBody (producer (advanced))	Used to specify if a null body is allowed during file writing. If set to true then an empty file will be created, when set to false, and attempting to send a null body to the file component, a GenericFileWriteException of 'Cannot write null body to file.' will be thrown. If the fileExist option is set to 'Override', then the file will be truncated, and if set to append the file will remain unchanged.	false	boolean

Name	Description	Default	Type
chmod (producer (advanced))	Specify the file permissions which is sent by the producer, the chmod value must be between 000 and 777; If there is a leading digit like in 0755 we will ignore it.		String
chmodDirectory (producer (advanced))	Specify the directory permissions used when the producer creates missing directories, the chmod value must be between 000 and 777; If there is a leading digit like in 0755 we will ignore it.		String
eagerDeleteTargetFile (producer (advanced))	Whether or not to eagerly delete any existing target file. This option only applies when you use fileExists=Override and the tempFileName option as well. You can use this to disable (set it to false) deleting the target file before the temp file is written. For example you may write big files and want the target file to exists during the temp file is being written. This ensure the target file is only deleted until the very last moment, just before the temp file is being renamed to the target filename. This option is also used to control whether to delete any existing files when fileExist=Move is enabled, and an existing file exists. If this option copyAndDeleteOnRenameFails false, then an exception will be thrown if an existing file existed, if its true, then the existing file is deleted before the move operation.	true	boolean
forceWrites (producer (advanced))	Whether to force syncing writes to the file system. You can turn this off if you do not want this level of guarantee, for example if writing to logs / audit logs etc; this would yield better performance.	true	boolean
keepLastModified (producer (advanced))	Will keep the last modified timestamp from the source file (if any). Will use the Exchange.FILE_LAST_MODIFIED header to located the timestamp. This header can contain either a java.util.Date or long with the timestamp. If the timestamp exists and the option is enabled it will set this timestamp on the written file. Note: This option only applies to the file producer. You cannot use this option with any of the ftp producers.	false	boolean
moveExistingFileStrategy (producer (advanced))	Strategy (Custom Strategy) used to move file with special naming token to use when fileExist=Move is configured. By default, there is an implementation used if no custom strategy is provided.		FileMoveExistingStrategy

Name	Description	Default	Type
autoCreate (advanced)	Automatically create missing directories in the file's pathname. For the file consumer, that means creating the starting directory. For the file producer, it means the directory the files should be written to.	true	boolean
bufferSize (advanced)	Buffer size in bytes used for writing files (or in case of FTP for downloading and uploading files).	131072	int
copyAndDeleteOnRenameFail (advanced)	Whether to fallback and do a copy and delete file, in case the file could not be renamed directly. This option is not available for the FTP component.	true	boolean
renameUsingCopy (advanced)	Perform rename operations using a copy and delete strategy. This is primarily used in environments where the regular rename operation is unreliable (e.g. across different file systems or networks). This option takes precedence over the <code>copyAndDeleteOnRenameFail</code> parameter that will automatically fall back to the copy and delete strategy, but only after additional delays.	false	boolean
synchronous (advanced)	Sets whether synchronous processing should be strictly used.	false	boolean
antExclude (filter)	Ant style filter exclusion. If both <code>antInclude</code> and <code>antExclude</code> are used, <code>antExclude</code> takes precedence over <code>antInclude</code> . Multiple exclusions may be specified in comma-delimited format.		String
antFilterCaseSensitive (filter)	Sets case sensitive flag on ant filter.	true	boolean
antInclude (filter)	Ant style filter inclusion. Multiple inclusions may be specified in comma-delimited format.		String
eagerMaxMessagesPerPoll (filter)	Allows for controlling whether the limit from <code>maxMessagesPerPoll</code> is eager or not. If eager then the limit is during the scanning of files. Where as false would scan all files, and then perform sorting. Setting this option to false allows for sorting all files first, and then limit the poll. Mind that this requires a higher memory usage as all file details are in memory to perform the sorting.	true	boolean

Name	Description	Default	Type
exclude (filter)	Is used to exclude files, if filename matches the regex pattern (matching is case in-sensitive). Notice if you use symbols such as plus sign and others you would need to configure this using the RAW() syntax if configuring this as an endpoint uri. See more details at configuring endpoint uris.		String
excludeExt (filter)	Is used to exclude files matching file extension name (case insensitive). For example to exclude bak files, then use excludeExt=bak. Multiple extensions can be separated by comma, for example to exclude bak and dat files, use excludeExt=bak,dat. Note that the file extension includes all parts, for example having a file named mydata.tar.gz will have extension as tar.gz. For more flexibility then use the include/exclude options.		String
filter (filter)	Pluggable filter as a org.apache.camel.component.file.GenericFileFilter class. Will skip files if filter returns false in its accept() method.		GenericFileFilter
filterDirectory (filter)	Filters the directory based on Simple language. For example to filter on current date, you can use a simple date pattern such as <code>\$\$\{date:now:yyyMMdd}</code> .		String
filterFile (filter)	Filters the file based on Simple language. For example to filter on file size, you can use <code>\$\$\{file:size} 5000</code> .		String
idempotent (filter)	Option to use the Idempotent Consumer EIP pattern to let Camel skip already processed files. Will by default use a memory based LRU Cache that holds 1000 entries. If noop=true then idempotent will be enabled as well to avoid consuming the same files over and over again.	false	Boolean
idempotentKey (filter)	To use a custom idempotent key. By default the absolute path of the file is used. You can use the File Language, for example to use the file name and file size, you can do: <code>idempotentKey=\$\$\{file:name}-\$\$\{file:size}</code> .		String
idempotentRepository (filter)	A pluggable repository org.apache.camel.spi.IdempotentRepository which by default use MemoryIdempotentRepository if none is specified and idempotent is true.		IdempotentRepository

Name	Description	Default	Type
include (filter)	Is used to include files, if filename matches the regex pattern (matching is case in-sensitive). Notice if you use symbols such as plus sign and others you would need to configure this using the RAW() syntax if configuring this as an endpoint uri. See more details at configuring endpoint uris.		String
includeExt (filter)	Is used to include files matching file extension name (case insensitive). For example to include txt files, then use includeExt=txt. Multiple extensions can be separated by comma, for example to include txt and xml files, use includeExt=txt,xml. Note that the file extension includes all parts, for example having a file named mydata.tar.gz will have extension as tar.gz. For more flexibility then use the include/exclude options.		String
maxDepth (filter)	The maximum depth to traverse when recursively processing a directory.	2147483647	int
maxMessagesPerPoll (filter)	To define a maximum messages to gather per poll. By default no maximum is set. Can be used to set a limit of e.g. 1000 to avoid when starting up the server that there are thousands of files. Set a value of 0 or negative to disabled it. Notice: If this option is in use then the File and FTP components will limit before any sorting. For example if you have 100000 files and use maxMessagesPerPoll=500, then only the first 500 files will be picked up, and then sorted. You can use the eagerMaxMessagesPerPoll option and set this to false to allow to scan all files first and then sort afterwards.		int
minDepth (filter)	The minimum depth to start processing when recursively processing a directory. Using minDepth=1 means the base directory. Using minDepth=2 means the first sub directory.		int
move (filter)	Expression (such as Simple Language) used to dynamically set the filename when moving it after processing. To move files into a .done subdirectory just enter .done.		String
exclusiveReadLockStrategy (lock)	Pluggable read-lock as a org.apache.camel.component.file.GenericFileExclusiveReadLockStrategy implementation.		GenericFileExclusiveReadLockStrategy

readLock (lock) Name	Description	none Default	String Type
	Used by consumer, to only poll the files if it has exclusive read-lock on the file (i.e. the file is not in-progress or being written). Camel will wait until the file lock is granted. This option provides the build in strategies: - none - No read lock is in use - markerFile - Camel creates a marker file (fileName.camellLock) and then holds a lock on it. This option is not available for the FTP component - changed - Changed is using file length/modification timestamp to detect whether the file is currently being copied or not. Will at least use 1 sec to determine this, so this option cannot consume files as fast as the others, but can be more reliable as the JDK IO API cannot always determine whether a file is currently being used by another process. The option readLockCheckInterval can be used to set the check frequency. - fileLock - is for using java.nio.channels.FileLock. This option is not avail for Windows OS and the FTP component. This approach should be avoided when accessing a remote file system via a mount/share unless that file system supports distributed file locks. - rename - rename is for using a try to rename the file as a test if we can get exclusive read-lock. - idempotent - (only for file component) idempotent is for using a idempotentRepository as the read-lock. This allows to use read locks that supports clustering if the idempotent repository implementation supports that. - idempotent-changed - (only for file component) idempotent-changed is for using a idempotentRepository and changed as the combined read-lock. This allows to use read locks that supports clustering if the idempotent repository implementation supports that. - idempotent-rename - (only for file component) idempotent-rename is for using a idempotentRepository and rename as the combined read-lock. This allows to use read locks that supports clustering if the idempotent repository implementation supports that. Notice: The various read locks is not all suited to work in clustered mode, where concurrent consumers on different nodes is competing for the same files on a shared file system. The markerFile using a close to atomic operation to create the empty marker file, but its not guaranteed to work in a cluster. The fileLock may work better but then the file system need to support distributed file locks, and so on. Using the idempotent read lock can support clustering if the idempotent repository supports clustering, such as Hazelcast Component or Infinispan. Enum values: ● none ● markerFile ● fileLock		

Name	● rename Description ● changed	Default	Type
	● idempotent ● idempotent-changed ● idempotent-rename		
readLockCheckInterval (lock)	Interval in millis for the read-lock, if supported by the read lock. This interval is used for sleeping between attempts to acquire the read lock. For example when using the changed read lock, you can set a higher interval period to cater for slow writes. The default of 1 sec. may be too fast if the producer is very slow writing the file. Notice: For FTP the default readLockCheckInterval is 5000. The readLockTimeout value must be higher than readLockCheckInterval, but a rule of thumb is to have a timeout that is at least 2 or more times higher than the readLockCheckInterval. This is needed to ensure that ample time is allowed for the read lock process to try to grab the lock before the timeout was hit.	1000	long
readLockDeleteOrphanLockFiles (lock)	Whether or not read lock with marker files should upon startup delete any orphan read lock files, which may have been left on the file system, if Camel was not properly shutdown (such as a JVM crash). If turning this option to false then any orphaned lock file will cause Camel to not attempt to pickup that file, this could also be due another node is concurrently reading files from the same shared directory.	true	boolean
readLockIdempotentReleaseAsync (lock)	Whether the delayed release task should be synchronous or asynchronous. See more details at the readLockIdempotentReleaseDelay option.	false	boolean
readLockIdempotentReleaseAsyncPoolSize (lock)	The number of threads in the scheduled thread pool when using asynchronous release tasks. Using a default of 1 core threads should be sufficient in almost all use-cases, only set this to a higher value if either updating the idempotent repository is slow, or there are a lot of files to process. This option is not in-use if you use a shared thread pool by configuring the readLockIdempotentReleaseExecutorService option. See more details at the readLockIdempotentReleaseDelay option.		int

Name	Description	Default	Type
readLockIdempotentReleaseDelay (lock)	Whether to delay the release task for a period of millis. This can be used to delay the release tasks to expand the window when a file is regarded as read-locked, in an active/active cluster scenario with a shared idempotent repository, to ensure other nodes cannot potentially scan and acquire the same file, due to race-conditions. By expanding the time-window of the release tasks helps prevents these situations. Note delaying is only needed if you have configured <code>readLockRemoveOnCommit</code> to true.		int
readLockIdempotentReleaseExecutorService (lock)	To use a custom and shared thread pool for asynchronous release tasks. See more details at the <code>readLockIdempotentReleaseDelay</code> option.		ScheduledExecutorService
readLockLoggingLevel (lock)	Logging level used when a read lock could not be acquired. By default a DEBUG is logged. You can change this level, for example to OFF to not have any logging. This option is only applicable for readLock of types: changed, fileLock, idempotent, idempotent-changed, idempotent-rename, rename. Enum values: ● TRACE ● DEBUG ● INFO ● WARN ● ERROR ● OFF	DEBUG	LoggingLevel
readLockMarkerFile (lock)	Whether to use marker file with the changed, rename, or exclusive read lock types. By default a marker file is used as well to guard against other processes picking up the same files. This behavior can be turned off by setting this option to false. For example if you do not want to write marker files to the file systems by the Camel application.	true	boolean
readLockMinAge (lock)	This option is applied only for readLock=changed. It allows to specify a minimum age the file must be before attempting to acquire the read lock. For example use <code>readLockMinAge=300s</code> to require the file is at last 5 minutes old. This can speedup the changed read lock as it will only attempt to acquire files which are at least that given age.	0	long

Name	Description	Default	Type
readLockMinLength (lock)	This option is applied only for readLock=changed. It allows you to configure a minimum file length. By default Camel expects the file to contain data, and thus the default value is 1. You can set this option to zero, to allow consuming zero-length files.	1	long
readLockRemoveOnCommit (lock)	This option is applied only for readLock=idempotent. It allows to specify whether to remove the file name entry from the idempotent repository when processing the file is succeeded and a commit happens. By default the file is not removed which ensures that any race-condition do not occur so another active node may attempt to grab the file. Instead the idempotent repository may support eviction strategies that you can configure to evict the file name entry after X minutes - this ensures no problems with race conditions. See more details at the readLockIdempotentReleaseDelay option.	false	boolean
readLockRemoveOnRollback (lock)	This option is applied only for readLock=idempotent. It allows to specify whether to remove the file name entry from the idempotent repository when processing the file failed and a rollback happens. If this option is false, then the file name entry is confirmed (as if the file did a commit).	true	boolean
readLockTimeout (lock)	Optional timeout in millis for the read-lock, if supported by the read-lock. If the read-lock could not be granted and the timeout triggered, then Camel will skip the file. At next poll Camel, will try the file again, and this time maybe the read-lock could be granted. Use a value of 0 or lower to indicate forever. Currently fileLock, changed and rename support the timeout. Notice: For FTP the default readLockTimeout value is 20000 instead of 10000. The readLockTimeout value must be higher than readLockCheckInterval, but a rule of thumb is to have a timeout that is at least 2 or more times higher than the readLockCheckInterval. This is needed to ensure that ample time is allowed for the read lock process to try to grab the lock before the timeout was hit.	10000	long
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.		int

Name	Description	Default	Type
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then <code>backoffIdleThreshold</code> and/or <code>backoffErrorThreshold</code> must also be configured.		int
delay (scheduler)	Milliseconds before the next poll.	500	long
greedy (scheduler)	If greedy is enabled, then the <code>ScheduledPollConsumer</code> will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts.	1000	long
repeatCount (scheduler)	Specifies a maximum limit of number of fires. So if you set it to 1, the scheduler will only fire once. If you set it to 5, it will only fire five times. A value of zero or negative means fire forever.	0	long
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that. Enum values: ● TRACE ● DEBUG ● INFO ● WARN ● ERROR ● OFF	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz component. Use value spring or quartz for built in scheduler.	none	Object

Name	Description	Default	Type
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for initialDelay and delay options. Enum values: • NANOSECONDS • MICROSECONDS • MILLISECONDS • SECONDS • MINUTES • HOURS • DAYS	MILLIS ECON DS	TimeUnit
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.	true	boolean
shuffle (sort)	To shuffle the list of files (sort in random order).	false	boolean
sortBy (sort)	Built-in sort by using the File Language. Supports nested sorts, so you can have a sort by file name and as a 2nd group sort by modified date.		String
sorter (sort)	Pluggable sorter as a java.util.Comparator class.		Comparator

NOTE

Default behavior for file producer

By default it will override any existing file, if one exist with the same name.

37.6. MOVE AND DELETE OPERATIONS

Any move or delete operations is executed after (post command) the routing has completed; so during processing of the **Exchange** the file is still located in the inbox folder.

Lets illustrate this with an example:

```
from("file://inbox?move=.done").to("bean:handleOrder");
```

When a file is dropped in the **inbox** folder, the file consumer notices this and creates a new **FileExchange** that is routed to the **handleOrder** bean. The bean then processes the **File** object. At this point in time the file is still located in the **inbox** folder. After the bean completes, and thus the route is completed, the file consumer will perform the move operation and move the file to the **.done** sub-folder.

The **move** and the **preMove** options are considered as a directory name (though if you use an expression such as [File Language](#), or [Simple](#) then the result of the expression evaluation is the file name to be used. For example, if you set:

```
move=../backup/copy-of-${file:name}
```

then that's using the [File](#) language which we use return the file name to be used), which can be either relative or absolute. If relative, the directory is created as a sub-folder from within the folder where the file was consumed.

By default, Camel will move consumed files to the **.camel** sub-folder relative to the directory where the file was consumed.

If you want to delete the file after processing, the route should be:

```
from("file://inbox?delete=true").to("bean:handleOrder");
```

We have introduced a **pre** move operation to move files **before** they are processed. This allows you to mark which files have been scanned as they are moved to this sub folder before being processed.

```
from("file://inbox?preMove=inprogress").to("bean:handleOrder");
```

You can combine the **pre** move and the regular move:

```
from("file://inbox?preMove=inprogress&move=.done").to("bean:handleOrder");
```

So in this situation, the file is in the **inprogress** folder when being processed and after it's processed, it's moved to the **.done** folder.

37.7. FINE GRAINED CONTROL OVER MOVE AND PREMOVE OPTION

The **move** and **preMove** options are Expression-based, so we have the full power of the [File Language](#) to do advanced configuration of the directory and name pattern.

Camel will, in fact, internally convert the directory name you enter into a [File Language](#) expression. So when we enter **move=.done** Camel will convert this into: **\${file:parent}/.done/\${file:onlyname}**. This is only done if Camel detects that you have not provided a **\$\{ }** in the option value yourself. So when you enter a **\$\{ }** Camel will **not** convert it and thus you have the full power.

So if we want to move the file into a backup folder with today's date as the pattern, we can do:

```
move=backup/${date:now:yyyyMMdd}/${file:name}
```

37.8. ABOUT MOVEFAILED

The **moveFailed** option allows you to move files that **could not** be processed successfully to another location such as an error folder of your choice. For example to move the files in an error folder with a

timestamp you can use `moveFailed=/error/${file:name.noext}-${date:now:yyyyMMddHHmmssSSS}.${file:ext}`.

37.9. MESSAGE HEADERS

The following headers are supported by this component:

37.9.1. File producer only

Header	Description
CamelFileName	Specifies the name of the file to write (relative to the endpoint directory). This name can be a String ; a String with a File Language or Simple language expression; or an Expression object. If it's null then Camel will auto-generate a filename based on the message unique ID.
CamelFileNameProduced	The actual absolute filepath (path + name) for the output file that was written. This header is set by Camel and its purpose is providing end-users with the name of the file that was written.
CamelOverruleFileName	Is used for overruling CamelFileName header and use the value instead (but only once, as the producer will remove this header after writing the file). The value can be only be a String. Notice that if the option fileName has been configured, then this is still being evaluated.

37.9.2. File consumer only

Header	Description
CamelFileName	Name of the consumed file as a relative file path with offset from the starting directory configured on the endpoint.
CamelFileNameOnly	Only the file name (the name with no leading paths).
CamelFileAbsolute	A boolean option specifying whether the consumed file denotes an absolute path or not. Should normally be false for relative paths. Absolute paths should normally not be used but we added to the move option to allow moving files to absolute paths. But can be used elsewhere as well.
CamelFileAbsolutePath	The absolute path to the file. For relative files this path holds the relative path instead.
CamelFilePath	The file path. For relative files this is the starting directory + the relative filename. For absolute files this is the absolute path.
CamelFileRelativePath	The relative path.
CamelFileParent	The parent path.

Header	Description
CamelFileLength	A long value containing the file size.
CamelFileLastModified	A Long value containing the last modified timestamp of the file.

37.10. BATCH CONSUMER

This component implements the Batch Consumer.

37.11. EXCHANGE PROPERTIES, FILE CONSUMER ONLY

As the file consumer implements the **BatchConsumer** it supports batching the files it polls. By batching we mean that Camel will add the following additional properties to the Exchange, so you know the number of files polled, the current index, and whether the batch is already completed.

Property	Description
CamelBatchSize	The total number of files that was polled in this batch.
CamelBatchIndex	The current index of the batch. Starts from 0.
CamelBatchComplete	A boolean value indicating the last Exchange in the batch. Is only true for the last entry.

This allows you for instance to know how many files exist in this batch and for instance let the `Aggregator2` aggregate this number of files.

37.12. USING CHARSET

The charset option allows for configuring an encoding of the files on both the consumer and producer endpoints. For example if you read utf-8 files, and want to convert the files to iso-8859-1, you can do:

```
from("file:inbox?charset=utf-8")
  .to("file:outbox?charset=iso-8859-1")
```

You can also use the **convertBodyTo** in the route. In the example below we have still input files in utf-8 format, but we want to convert the file content to a byte array in iso-8859-1 format. And then let a bean process the data. Before writing the content to the outbox folder using the current charset.

```
from("file:inbox?charset=utf-8")
  .convertBodyTo(byte[].class, "iso-8859-1")
  .to("bean:myBean")
  .to("file:outbox");
```

If you omit the charset on the consumer endpoint, then Camel does not know the charset of the file, and would by default use "UTF-8". However you can configure a JVM system property to override and use a different default encoding with the key **org.apache.camel.default.charset**.

In the example below this could be a problem if the files is not in UTF-8 encoding, which would be the default encoding for read the files.

In this example when writing the files, the content has already been converted to a byte array, and thus would write the content directly as is (without any further encodings).

```
from("file:inbox")
  .convertBodyTo(byte[].class, "iso-8859-1")
  .to("bean:myBean")
  .to("file:outbox");
```

You can also override and control the encoding dynamic when writing files, by setting a property on the exchange with the key **Exchange.CHARSET_NAME**. For example in the route below we set the property with a value from a message header.

```
from("file:inbox")
  .convertBodyTo(byte[].class, "iso-8859-1")
  .to("bean:myBean")
  .setProperty(Exchange.CHARSET_NAME, header("someCharsetHeader"))
  .to("file:outbox");
```

We suggest to keep things simpler, so if you pickup files with the same encoding, and want to write the files in a specific encoding, then favor to use the **charset** option on the endpoints.

Notice that if you have explicit configured a **charset** option on the endpoint, then that configuration is used, regardless of the **Exchange.CHARSET_NAME** property.

If you have some issues then you can enable DEBUG logging on **org.apache.camel.component.file**, and Camel logs when it reads/write a file using a specific charset. For example the route below will log the following:

```
from("file:inbox?charset=utf-8")
  .to("file:outbox?charset=iso-8859-1")
```

And the logs:

```
DEBUG GenericFileConverter      - Read file /Users/davsclaus/workspace/camel/camel-
core/target/charset/input/input.txt with charset utf-8
DEBUG FileOperations            - Using Reader to write file: target/charset/output.txt with charset:
iso-8859-1
```

37.13. COMMON GOTCHAS WITH FOLDER AND FILENAMES

When Camel is producing files (writing files) there are a few gotchas affecting how to set a filename of your choice. By default, Camel will use the message ID as the filename, and since the message ID is normally a unique generated ID, you will end up with filenames such as: **ID-MACHINENAME-2443-1211718892437-1-0**. If such a filename is not desired, then you must provide a filename in the **CamelFileName** message header. The constant, **Exchange.FILE_NAME**, can also be used.

The sample code below produces files using the message ID as the filename:

```
from("direct:report").to("file:target/reports");
```

To use **report.txt** as the filename you have to do:

```
from("direct:report").setHeader(Exchange.FILE_NAME, constant("report.txt")).to("file:target/reports");
```

- the same as above, but with **CamelFileName**:

```
from("direct:report").setHeader("CamelFileName", constant("report.txt")).to("file:target/reports");
```

And a syntax where we set the filename on the endpoint with the **fileName** URI option.

```
from("direct:report").to("file:target/reports/?fileName=report.txt");
```

37.14. FILENAME EXPRESSION

Filename can be set either using the **expression** option or as a string-based [File](#) language expression in the **CamelFileName** header. See the [File](#) language for syntax and samples.

37.15. CONSUMING FILES FROM FOLDERS WHERE OTHERS DROP FILES DIRECTLY

Beware if you consume files from a folder where other applications write files to directly. Take a look at the different readLock options to see what suits your use cases. The best approach is however to write to another folder and after the write move the file in the drop folder. However if you write files directly to the drop folder then the option changed could better detect whether a file is currently being written/copied as it uses a file changed algorithm to see whether the file size / modification changes over a period of time. The other readLock options rely on Java File API that sadly is not always very good at detecting this. You may also want to look at the doneFileName option, which uses a marker file (done file) to signal when a file is done and ready to be consumed.

37.16. USING DONE FILES

See also section *writing done files* below.

If you want only to consume files when a done file exists, then you can use the **doneFileName** option on the endpoint.

```
from("file:bar?doneFileName=done");
```

Will only consume files from the bar folder, if a done *file* exists in the same directory as the target files. Camel will automatically delete the *done file* when it's done consuming the files. Camel does not delete automatically the *done file* if **noop=true** is configured.

However it is more common to have one *done file* per target file. This means there is a 1:1 correlation. To do this you must use dynamic placeholders in the **doneFileName** option. Currently Camel supports the following two dynamic tokens: **file:name** and **file:name.noext** which must be enclosed in `${ }`. The consumer only supports the static part of the *done file* name as either prefix or suffix (not both).

```
from("file:bar?doneFileName=${file:name}.done");
```

In this example only files will be polled if there exists a done file with the name *file name.done*. For example

- **hello.txt** - is the file to be consumed

- **hello.txt.done** – is the associated done file

You can also use a prefix for the done file, such as:

```
from("file:bar?doneFileName=ready-${file:name}");
```

- **hello.txt** – is the file to be consumed
- **ready-hello.txt** – is the associated done file

37.17. WRITING DONE FILES

After you have written a file you may want to write an additional *donefile* as a kind of marker, to indicate to others that the file is finished and has been written. To do that you can use the **doneFileName** option on the file producer endpoint.

```
.to("file:bar?doneFileName=done");
```

Will simply create a file named **done** in the same directory as the target file.

However it is more common to have one done file per target file. This means there is a 1:1 correlation. To do this you must use dynamic placeholders in the **doneFileName** option. Currently Camel supports the following two dynamic tokens: **file:name** and **file:name.noext** which must be enclosed in `${ }`.

```
.to("file:bar?doneFileName=done-${file:name}");
```

Will for example create a file named **done-foo.txt** if the target file was **foo.txt** in the same directory as the target file.

```
.to("file:bar?doneFileName=${file:name}.done");
```

Will for example create a file named **foo.txt.done** if the target file was **foo.txt** in the same directory as the target file.

```
.to("file:bar?doneFileName=${file:name.noext}.done");
```

Will for example create a file named **foo.done** if the target file was **foo.txt** in the same directory as the target file.

37.18. SAMPLES

37.18.1. Read from a directory and write to another directory

```
from("file://inputdir/?delete=true").to("file://outputdir")
```

37.18.2. Read from a directory and write to another directory using a overrule dynamic name

```
from("file://inputdir/?delete=true").to("file://outputdir?overruleFile=copy-of-${file:name}")
```

Listen on a directory and create a message for each file dropped there. Copy the contents to the **outputdir** and delete the file in the **inputdir**.

37.18.3. Reading recursively from a directory and writing to another

```
from("file://inputdir/?recursive=true&delete=true").to("file://outputdir")
```

Listen on a directory and create a message for each file dropped there. Copy the contents to the **outputdir** and delete the file in the **inputdir**. Will scan recursively into sub-directories. Will lay out the files in the same directory structure in the **outputdir** as the **inputdir**, including any sub-directories.

```
inputdir/foo.txt  
inputdir/sub/bar.txt
```

Will result in the following output layout:

```
outputdir/foo.txt  
outputdir/sub/bar.txt
```

37.19. USING FLATTEN

If you want to store the files in the outputdir directory in the same directory, disregarding the source directory layout (e.g. to flatten out the path), you just add the **flatten=true** option on the file producer side:

```
from("file://inputdir/?recursive=true&delete=true").to("file://outputdir?flatten=true")
```

Will result in the following output layout:

```
outputdir/foo.txt  
outputdir/bar.txt
```

37.20. READING FROM A DIRECTORY AND THE DEFAULT MOVE OPERATION

Camel will by default move any processed file into a **.camel** subdirectory in the directory the file was consumed from.

```
from("file://inputdir/?recursive=true&delete=true").to("file://outputdir")
```

Affects the layout as follows:

before

```
inputdir/foo.txt  
inputdir/sub/bar.txt
```

after

```
inputdir/.camel/foo.txt  
inputdir/sub/.camel/bar.txt
```

```
outputdir/foo.txt
outputdir/sub/bar.txt
```

37.21. READ FROM A DIRECTORY AND PROCESS THE MESSAGE IN JAVA

```
from("file://inputdir/").process(new Processor() {
    public void process(Exchange exchange) throws Exception {
        Object body = exchange.getIn().getBody();
        // do some business logic with the input body
    }
});
```

The body will be a **File** object that points to the file that was just dropped into the **inputdir** directory.

37.22. WRITING TO FILES

Camel is of course also able to write files, i.e. produce files. In the sample below we receive some reports on the SEDA queue that we process before they are being written to a directory.

37.22.1. Write to subdirectory using **Exchange.FILE_NAME**

Using a single route, it is possible to write a file to any number of subdirectories. If you have a route setup as such:

```
<route>
  <from uri="bean:myBean"/>
  <to uri="file:/rootDirectory"/>
</route>
```

You can have **myBean** set the header **Exchange.FILE_NAME** to values such as:

```
Exchange.FILE_NAME = hello.txt => /rootDirectory/hello.txt
Exchange.FILE_NAME = foo/bye.txt => /rootDirectory/foo/bye.txt
```

This allows you to have a single route to write files to multiple destinations.

37.22.2. Writing file through the temporary directory relative to the final destination

Sometime you need to temporarily write the files to some directory relative to the destination directory. Such situation usually happens when some external process with limited filtering capabilities is reading from the directory you are writing to. In the example below files will be written to the **/var/myapp/filesInProgress** directory and after data transfer is done, they will be atomically moved to the **/var/myapp/finalDirectory** directory.

```
from("direct:start").
  to("file:///var/myapp/finalDirectory?tempPrefix=./filesInProgress/");
```

37.23. USING EXPRESSION FOR FILENAMES

In this sample we want to move consumed files to a backup folder using today's date as a sub-folder name:

```
from("file://inbox?move=backup/${date:now:yyyyMMdd}/${file:name}").to("...");
```

See [File language](#) for more samples.

37.24. AVOIDING READING THE SAME FILE MORE THAN ONCE (IDEMPOTENT CONSUMER)

Camel supports Idempotent Consumer directly within the component so it will skip already processed files. This feature can be enabled by setting the **idempotent=true** option.

```
from("file://inbox?idempotent=true").to("...");
```

Camel uses the absolute file name as the idempotent key, to detect duplicate files. You can customize this key by using an expression in the `idempotentKey` option. For example to use both the name and the file size as the key

```
<route>
  <from uri="file://inbox?idempotent=true&idempotentKey=${file:name}-${file:size}"/>
  <to uri="bean:processInbox"/>
</route>
```

By default Camel uses a in memory based store for keeping track of consumed files, it uses a least recently used cache holding up to 1000 entries. You can plugin your own implementation of this store by using the **idempotentRepository** option using the `#` sign in the value to indicate it's a referring to a bean in the Registry with the specified **id**.

```
<!-- define our store as a plain spring bean -->
<bean id="myStore" class="com.mycompany.MyIdempotentStore"/>

<route>
  <from uri="file://inbox?idempotent=true&idempotentRepository=#myStore"/>
  <to uri="bean:processInbox"/>
</route>
```

Camel will log at **DEBUG** level if it skips a file because it has been consumed before:

```
DEBUG FileConsumer is idempotent and the file has been consumed before. Will skip this file:
target\idempotent\report.txt
```

37.25. USING A FILE BASED IDEMPOTENT REPOSITORY

In this section we will use the file based idempotent repository **org.apache.camel.processor.idempotent.FileIdempotentRepository** instead of the in-memory based that is used as default.

This repository uses a 1st level cache to avoid reading the file repository. It will only use the file repository to store the content of the 1st level cache. Thereby the repository can survive server restarts. It will load the content of the file into the 1st level cache upon startup. The file structure is very simple as

it stores the key in separate lines in the file. By default, the file store has a size limit of 1mb. When the file grows larger Camel will truncate the file store, rebuilding the content by flushing the 1st level cache into a fresh empty file.

We configure our repository using Spring XML creating our file idempotent repository and define our file consumer to use our repository with the **idempotentRepository** using # sign to indicate Registry lookup:

37.26. USING A JPA BASED IDEMPOTENT REPOSITORY

In this section we will use the JPA based idempotent repository instead of the in-memory based that is used as default.

First we need a persistence-unit in **META-INF/persistence.xml** where we need to use the class **org.apache.camel.processor.idempotent.jpa.MessageProcessed** as model.

```
<persistence-unit name="idempotentDb" transaction-type="RESOURCE_LOCAL">
  <class>org.apache.camel.processor.idempotent.jpa.MessageProcessed</class>

  <properties>
    <property name="openjpa.ConnectionURL" value="jdbc:derby:target/idempotentTest;create=true"/>
    <property name="openjpa.ConnectionDriverName"
value="org.apache.derby.jdbc.EmbeddedDriver"/>
    <property name="openjpa.jdbc.SynchronizeMappings" value="buildSchema"/>
    <property name="openjpa.Log" value="DefaultLevel=WARN, Tool=INFO"/>
    <property name="openjpa.Multithreaded" value="true"/>
  </properties>
</persistence-unit>
```

Next, we can create our JPA idempotent repository in the spring XML file as well:

```
<!-- we define our jpa based idempotent repository we want to use in the file consumer -->
<bean id="jpaStore" class="org.apache.camel.processor.idempotent.jpa.JpaMessageIdRepository">
  <!-- Here we refer to the entityManagerFactory -->
  <constructor-arg index="0" ref="entityManagerFactory"/>
  <!-- This 2nd parameter is the name (= a category name).
      You can have different repositories with different names -->
  <constructor-arg index="1" value="FileConsumer"/>
</bean>
```

And yes then we just need to refer to the **jpaStore** bean in the file consumer endpoint using the **idempotentRepository** using the # syntax option:

```
<route>
  <from uri="file://inbox?idempotent=true&idempotentRepository=#jpaStore"/>
  <to uri="bean:processInbox"/>
</route>
```

37.27. FILTER USING ORG.APACHE.CAMEL.COMPONENT.FILE.GENERICFILEFILTER

Camel supports pluggable filtering strategies. You can then configure the endpoint with such a filter to skip certain files being processed.

In the sample we have built our own filter that skips files starting with **skip** in the filename:

And then we can configure our route using the **filter** attribute to reference our filter (using # notation) that we have defined in the spring XML file:

```
<!-- define our filter as a plain spring bean -->
<bean id="myFilter" class="com.mycompany.MyFileFilter"/>

<route>
  <from uri="file://inbox?filter=#myFilter"/>
  <to uri="bean:processInbox"/>
</route>
```

37.28. FILTERING USING ANT PATH MATCHER

The ANT path matcher is based on [AntPathMatcher](#).

The file paths is matched with the following rules:

- **?** matches one character
- ***** matches zero or more characters
- ****** matches zero or more directories in a path

The **antInclude** and **antExclude** options make it easy to specify ANT style include/exclude without having to define the filter. See the URI options above for more information. The sample below demonstrates how to use it.

NOTE

When using **minDepth/maxDepth** with the combination of **recursive=true**, **antExclude=...**, and **readLockDeleteOrphanLockFiles=true** results in scanning all the files/subfolders deeper than value mentioned in the **maxDepth**. The workaround is to configure **readLockDeleteOrphanLockFiles=false**.

37.28.1. Sorting using Comparator

Camel supports pluggable sorting strategies. This strategy it to use the build in **java.util.Comparator** in Java. You can then configure the endpoint with such a comparator and have Camel sort the files before being processed.

In the sample we have built our own comparator that just sorts by file name:

And then we can configure our route using the **sorter** option to reference to our sorter (**mySorter**) we have defined in the spring XML file:

```
<!-- define our sorter as a plain spring bean -->
<bean id="mySorter" class="com.mycompany.MyFileSorter"/>

<route>
  <from uri="file://inbox?sorter=#mySorter"/>
  <to uri="bean:processInbox"/>
</route>
```

NOTE

URI options can reference beans using the # syntax

In the Spring DSL route above notice that we can refer to beans in the Registry by prefixing the id with **#**. So writing **sorter=#mySorter**, will instruct Camel to go look in the Registry for a bean with the ID, **mySorter**.

37.28.2. Sorting using sortBy

Camel supports pluggable sorting strategies. This strategy it to use the [File](#) language to configure the sorting. The **sortBy** option is configured as follows:

```
sortBy=group 1;group 2;group 3;...
```

Where each group is separated with semi colon. In the simple situations you just use one group, so a simple example could be:

```
sortBy=file:name
```

This will sort by file name, you can reverse the order by prefixing **reverse:** to the group, so the sorting is now Z..A:

```
sortBy=reverse:file:name
```

As we have the full power of [File](#) language we can use some of the other parameters, so if we want to sort by file size we do:

```
sortBy=file:length
```

You can configure to ignore the case, using **ignoreCase:** for string comparison, so if you want to use file name sorting but to ignore the case then we do:

```
sortBy=ignoreCase:file:name
```

You can combine ignore case and reverse, however reverse must be specified first:

```
sortBy=reverse:ignoreCase:file:name
```

In the sample below we want to sort by last modified file, so we do:

```
sortBy=file:modified
```

And then we want to group by name as a 2nd option so files with same modification is sorted by name:

```
sortBy=file:modified;file:name
```

Now there is an issue here, can you spot it? Well the modified timestamp of the file is too fine as it will be in milliseconds, but what if we want to sort by date only and then subgroup by name?

Well as we have the true power of [File](#) language we can use its date command that supports patterns. So this can be solved as:

```
sortBy=date:file:yyyyMMdd;file:name
```

Yeah, that is pretty powerful, oh by the way you can also use reverse per group, so we could reverse the file names:

```
sortBy=date:file:yyyyMMdd;reverse:file:name
```

37.29. USING GENERICFILEPROCESSSTRATEGY

The option **processStrategy** can be used to use a custom **GenericFileProcessStrategy** that allows you to implement your own *begin*, *commit* and *rollback* logic.

For instance lets assume a system writes a file in a folder you should consume. But you should not start consuming the file before another *ready* file has been written as well.

So by implementing our own **GenericFileProcessStrategy** we can implement this as:

- In the **begin()** method we can test whether the special *ready* file exists. The begin method returns a **boolean** to indicate if we can consume the file or not.
- In the **abort()** method special logic can be executed in case the **begin** operation returned **false**, for example to cleanup resources etc.
- in the **commit()** method we can move the actual file and also delete the *ready* file.

37.30. USING FILTER

The **filter** option allows you to implement a custom filter in Java code by implementing the **org.apache.camel.component.file.GenericFileFilter** interface. This interface has an **accept** method that returns a boolean. Return **true** to include the file, and **false** to skip the file. There is a **isDirectory** method on **GenericFile** whether the file is a directory. This allows you to filter unwanted directories, to avoid traversing down unwanted directories.

For example to skip any directories which starts with **"skip"** in the name, can be implemented as follows:

37.31. USING BRIDGEERRORHANDLER

If you want to use the Camel Error Handler to deal with any exception occurring in the file consumer, then you can enable the **bridgeErrorHandler** option as shown below:

```
// to handle any IOException being thrown
onException(IOException.class)
    .handled(true)
    .log("IOException occurred due: ${exception.message}")
    .transform().simple("Error ${exception.message}")
    .to("mock:error");

// this is the file route that pickup files, notice how we bridge the consumer to use the Camel routing
// error handler
// the exclusiveReadLockStrategy is only configured because this is from an unit test, so we use that
// to simulate exceptions
from("file:target/nospace?bridgeErrorHandler=true")
    .convertBodyTo(String.class)
    .to("mock:result");
```

So all you have to do is to enable this option, and the error handler in the route will take it from there.

IMPORTANT

When using **bridgeErrorHandler**

When using `bridgeErrorHandler`, then interceptors, `OnCompletions` does **not** apply. The Exchange is processed directly by the Camel Error Handler, and does not allow prior actions such as interceptors, `onCompletion` to take action.

37.32. DEBUG LOGGING

This component has log level **TRACE** that can be helpful if you have problems.

37.33. SPRING BOOT AUTO-CONFIGURATION

The component supports 11 options, which are listed below.

Name	Description	Default	Type
<code>camel.cluster.file.acquire-lock-delay</code>	The time to wait before starting to try to acquire lock.		String
<code>camel.cluster.file.acquire-lock-interval</code>	The time to wait between attempts to try to acquire lock.		String
<code>camel.cluster.file.attributes</code>	Custom service attributes.		Map
<code>camel.cluster.file.enabled</code>	Sets if the file cluster service should be enabled or not, default is false.	false	Boolean
<code>camel.cluster.file.id</code>	Cluster Service ID.		String
<code>camel.cluster.file.order</code>	Service lookup order/priority.		Integer
<code>camel.cluster.file.root</code>	The root path.		String
<code>camel.component.file.autowired-enabled</code>	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.file.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.file.enabled	Whether to enable auto configuration of the file component. This is enabled by default.		Boolean
camel.component.file.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 38. FILE LANGUAGE

The File Expression Language is an extension to the language, adding file related capabilities. These capabilities are related to common use cases working with file path and names. The goal is to allow expressions to be used with the

components for setting dynamic file patterns for both consumer and producer.

NOTE

The file language is merged with language which means you can use all the file syntax directly within the simple language.

38.1. DEPENDENCIES

The File language is part of **camel-core**.

When using **file** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-core-starter</artifactId>
</dependency>
```

38.2. FILE LANGUAGE OPTIONS

The File language supports 2 options, which are listed below.

Name	Default	Java Type	Description
resultType		String	Sets the class name of the result type (type from output).
trim		Boolean	Whether to trim the value to remove leading and trailing whitespaces and line breaks.

38.3. SYNTAX

This language is an **extension** to the language so the syntax applies also. So the table below only lists the additional file related functions.

All the file tokens use the same expression name as the method on the **java.io.File** object, for instance **file:absolute** refers to the **java.io.File.getAbsolute()** method. Notice that not all expressions are supported by the current Exchange. For instance the component supports some options, whereas the File component supports all of them.

Expression	Type	File Consumer	File Producer	FTP Consumer	FTP Producer	Description
file:name	String	yes	no	yes	no	refers to the file name (is relative to the starting directory, see note below)
file:name.ext	String	yes	no	yes	no	refers to the file extension only
file:name.ext.single	String	yes	no	yes	no	refers to the file extension. If the file extension has multiple dots, then this expression strips and only returns the last part.
file:name.noext	String	yes	no	yes	no	refers to the file name with no extension (is relative to the starting directory, see note below)
file:name.noext.single	String	yes	no	yes	no	refers to the file name with no extension (is relative to the starting directory, see note below). If the file extension has multiple dots, then this expression strips only the last part, and keep the others.
file:only name	String	yes	no	yes	no	refers to the file name only with no leading paths.
file:only name.noext	String	yes	no	yes	no	refers to the file name only with no extension and with no leading paths.

Expression	Type	File Consumer	File Producer	FTP Consumer	FTP Producer	Description
file:onlyname.noext.single	String	yes	no	yes	no	refers to the file name only with no extension and with no leading paths. If the file extension has multiple dots, then this expression strips only the last part, and keep the others.
file:ext	String	yes	no	yes	no	refers to the file extension only
file:parent	String	yes	no	yes	no	refers to the file parent
file:path	String	yes	no	yes	no	refers to the file path
file:absolute	Boolean	yes	no	no	no	refers to whether the file is regarded as absolute or relative
file:absolute.path	String	yes	no	no	no	refers to the absolute file path
file:length	Long	yes	no	yes	no	refers to the file length returned as a Long type
file:size	Long	yes	no	yes	no	refers to the file length returned as a Long type
file:modified	Date	yes	no	yes	no	Refers to the file last modified returned as a Date type

Expression	Type	File Consumer	File Producer	FTP Consumer	FTP Producer	Description
date:command:pattern_	String	yes	yes	yes	yes	for date formatting using the java.text.SimpleDateFormat patterns. Is an extension to the language. Additional command is: file (consumers only) for the last modified timestamp of the file. Notice: all the commands from the language can also be used.

38.4. FILE TOKEN EXAMPLE

38.4.1. Relative paths

We have a **java.io.File** handle for the file **hello.txt** in the following **relative** directory: **.filelanguage\test**. And we configure our endpoint to use this starting directory **.filelanguage**. The file tokens will return as:

Expression	Returns
file:name	test\hello.txt
file:name.ext	txt
file:name.noext	test\hello
file:onlyname	hello.txt
file:onlyname.noext	hello
file:ext	txt
file:parent	filelanguage\test
file:path	filelanguage\test\hello.txt
file:absolute	false
file:absolute.path	\workspace\camel\camel-core\target\filelanguage\test\hello.txt

38.4.2. Absolute paths

We have a **java.io.File** handle for the file **hello.txt** in the following **absolute** directory: **\workspace\camel\camel-core\target\filelanguage\test**. And we configure out endpoint to use the absolute starting directory **\workspace\camel\camel-core\target\filelanguage**. The file tokens will return as:

Expression	Returns
file:name	test\hello.txt
file:name.ext	txt
file:name.noext	test\hello
file:onlyname	hello.txt
file:onlyname.noext	hello
file:ext	txt
file:parent	\workspace\camel\camel-core\target\filelanguage\test
file:path	\workspace\camel\camel-core\target\filelanguage\test\hello.txt
file:absolute	true
file:absolute.path	\workspace\camel\camel-core\target\filelanguage\test\hello.txt

38.5. SAMPLES

You can enter a fixed file name such as **myfile.txt**:

```
fileName="myfile.txt"
```

Let's assume we use the file consumer to read files and want to move the read files to back up folder with the current date as a sub folder. This can be done using an expression like:

```
fileName="backup/${date:now:yyyyMMdd}/${file:name.noext}.bak"
```

relative folder names are also supported so suppose the backup folder should be a sibling folder then you can append **..** as shown:

```
fileName="../backup/${date:now:yyyyMMdd}/${file:name.noext}.bak"
```

As this is an extension to the language we have access to all the goodies from this language also, so in this use case we want to use the `in.header.type` as a parameter in the dynamic expression:

```
fileName="../../backup/${date:now:yyyyMMdd}/type-${in.header.type}/backup-of-${file:name.noext}.bak"
```

If you have a custom date you want to use in the expression then Camel supports retrieving dates from the message header:

```
fileName="orders/order-${in.header.customerId}-${date:in.header.orderDate:yyyyMMdd}.xml"
```

And finally we can also use a bean expression to invoke a POJO class that generates some String output (or convertible to String) to be used:

```
fileName="uniquefile-${bean:myguidgenerator.generateid}.txt"
```

Of course all this can be combined in one expression where you can use the `and` language in one combined expression. This is pretty powerful for those common file path patterns.

38.6. SPRING BOOT AUTO-CONFIGURATION

The component supports 147 options, which are listed below.

Name	Description	Default	Type
<code>camel.cloud.consul.service-discovery.acl-token</code>	Sets the ACL token to be used with Consul.		String
<code>camel.cloud.consul.service-discovery.block-seconds</code>	The seconds to wait for a watch event, default 10 seconds.	10	Integer
<code>camel.cloud.consul.service-discovery.configurations</code>	Define additional configuration definitions.		Map
<code>camel.cloud.consul.service-discovery.connect-timeout-millis</code>	Connect timeout for OkHttpClient.		Long
<code>camel.cloud.consul.service-discovery.datacenter</code>	The data center.		String

Name	Description	Default	Type
<code>camel.cloud.consul.service-discovery.enabled</code>	Enable the component.	true	Boolean
<code>camel.cloud.consul.service-discovery.password</code>	Sets the password to be used for basic authentication.		String
<code>camel.cloud.consul.service-discovery.properties</code>	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in <code>com.netflix.client.config.CommonClientConfigKey</code> .		Map
<code>camel.cloud.consul.service-discovery.read-timeout-millis</code>	Read timeout for OkHttpClient.		Long
<code>camel.cloud.consul.service-discovery.url</code>	The Consul agent URL.		String
<code>camel.cloud.consul.service-discovery.username</code>	Sets the username to be used for basic authentication.		String
<code>camel.cloud.consul.service-discovery.write-timeout-millis</code>	Write timeout for OkHttpClient.		Long
<code>camel.cloud.dns.service-discovery.configurations</code>	Define additional configuration definitions.		Map
<code>camel.cloud.dns.service-discovery.domain</code>	The domain name;.		String
<code>camel.cloud.dns.service-discovery.enabled</code>	Enable the component.	true	Boolean

Name	Description	Default	Type
<code>camel.cloud.dns.service-discovery.properties</code>	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in <code>com.netflix.client.config.CommonClientConfigKey</code> .		Map
<code>camel.cloud.dns.service-discovery.proto</code>	The transport protocol of the desired service.	<code>_tcp</code>	String
<code>camel.cloud.etcd.service-discovery.configurations</code>	Define additional configuration definitions.		Map
<code>camel.cloud.etcd.service-discovery.enabled</code>	Enable the component.	<code>true</code>	Boolean
<code>camel.cloud.etcd.service-discovery.password</code>	The password to use for basic authentication.		String
<code>camel.cloud.etcd.service-discovery.properties</code>	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in <code>com.netflix.client.config.CommonClientConfigKey</code> .		Map
<code>camel.cloud.etcd.service-discovery.service-path</code>	The path to look for for service discovery.	<code>/services/</code>	String
<code>camel.cloud.etcd.service-discovery.timeout</code>	To set the maximum time an action could take to complete.		Long
<code>camel.cloud.etcd.service-discovery.type</code>	To set the discovery type, valid values are on-demand and watch.	<code>on-demand</code>	String
<code>camel.cloud.etcd.service-discovery.uris</code>	The URIs the client can connect to.		String

Name	Description	Default	Type
<code>camel.cloud.etcd.service-discovery.user-name</code>	The user name to use for basic authentication.		String
<code>camel.cloud.kubernetes.service-discovery.api-version</code>	Sets the API version when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.ca-cert-data</code>	Sets the Certificate Authority data when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.ca-cert-file</code>	Sets the Certificate Authority data that are loaded from the file when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.client-cert-data</code>	Sets the Client Certificate data when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.client-cert-file</code>	Sets the Client Certificate data that are loaded from the file when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.client-key-algo</code>	Sets the Client Keystore algorithm, such as RSA when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.client-key-data</code>	Sets the Client Keystore data when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.client-key-file</code>	Sets the Client Keystore data that are loaded from the file when using client lookup.		String

Name	Description	Default	Type
<code>camel.cloud.kubernetes.service-discovery.client-key-passphrase</code>	Sets the Client Keystore passphrase when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.configurations</code>	Define additional configuration definitions.		Map
<code>camel.cloud.kubernetes.service-discovery.dns-domain</code>	Sets the DNS domain to use for DNS lookup.		String
<code>camel.cloud.kubernetes.service-discovery.enabled</code>	Enable the component.	true	Boolean
<code>camel.cloud.kubernetes.service-discovery.lookup</code>	How to perform service lookup. Possible values: client, dns, environment. When using client, then the client queries the kubernetes master to obtain a list of active pods that provides the service, and then random (or round robin) select a pod. When using dns the service name is resolved as name.namespace.svc.dnsDomain. When using dnssrv the service name is resolved with SRV query forsvc... When using environment then environment variables are used to lookup the service. By default environment is used.	environment	String
<code>camel.cloud.kubernetes.service-discovery.master-url</code>	Sets the URL to the master when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.namespace</code>	Sets the namespace to use. Will by default use namespace from the ENV variable KUBERNETES_MASTER.		String
<code>camel.cloud.kubernetes.service-discovery.oauth-token</code>	Sets the OAUTH token for authentication (instead of username/password) when using client lookup.		String

Name	Description	Default	Type
<code>camel.cloud.kubernetes.service-discovery.password</code>	Sets the password for authentication when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.port-name</code>	Sets the Port Name to use for DNS/DNSSRV lookup.		String
<code>camel.cloud.kubernetes.service-discovery.port-protocol</code>	Sets the Port Protocol to use for DNS/DNSSRV lookup.		String
<code>camel.cloud.kubernetes.service-discovery.properties</code>	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in <code>com.netflix.client.config.CommonClientConfigKey</code> .		Map
<code>camel.cloud.kubernetes.service-discovery.trust-certs</code>	Sets whether to turn on trust certificate check when using client lookup.	false	Boolean
<code>camel.cloud.kubernetes.service-discovery.username</code>	Sets the username for authentication when using client lookup.		String
<code>camel.cloud.ribbon.load-balancer.client-name</code>	Sets the Ribbon client name.		String
<code>camel.cloud.ribbon.load-balancer.configurations</code>	Define additional configuration definitions.		Map
<code>camel.cloud.ribbon.load-balancer.enabled</code>	Enable the component.	true	Boolean

Name	Description	Default	Type
<code>camel.cloud.ribbon.load-balancer.namespace</code>	The namespace.		String
<code>camel.cloud.ribbon.load-balancer.password</code>	The password.		String
<code>camel.cloud.ribbon.load-balancer.properties</code>	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in <code>com.netflix.client.config.CommonClientConfigKey</code> .		Map
<code>camel.cloud.ribbon.load-balancer.username</code>	The username.		String
<code>camel.hystrix.allow-maximum-size-to-diverge-from-core-size</code>	Allows the configuration for <code>maximumSize</code> to take effect. That value can then be equal to, or higher, than <code>coreSize</code> .	false	Boolean
<code>camel.hystrix.circuit-breaker-enabled</code>	Whether to use a <code>HystrixCircuitBreaker</code> or not. If false no circuit-breaker logic will be used and all requests permitted. This is similar in effect to <code>circuitBreakerForceClosed()</code> except that continues tracking metrics and knowing whether it should be open/closed, this property results in not even instantiating a circuit-breaker.	true	Boolean
<code>camel.hystrix.circuit-breaker-error-threshold-percentage</code>	Error percentage threshold (as whole number such as 50) at which point the circuit breaker will trip open and reject requests. It will stay tripped for the duration defined in <code>circuitBreakerSleepWindowInMilliseconds</code> ; The error percentage this is compared against comes from <code>HystrixCommandMetrics.getHealthCounts()</code> .	50	Integer

Name	Description	Default	Type
camel.hystrix.circuit-breaker-force-closed	If true the <code>HystrixCircuitBreaker#allowRequest()</code> will always return true to allow requests regardless of the error percentage from <code>HystrixCommandMetrics.getHealthCounts()</code> . The <code>circuitBreakerForceOpen()</code> property takes precedence so if it set to true this property does nothing.	false	Boolean
camel.hystrix.circuit-breaker-force-open	If true the <code>HystrixCircuitBreaker.allowRequest()</code> will always return false, causing the circuit to be open (tripped) and reject all requests. This property takes precedence over <code>circuitBreakerForceClosed()</code> .	false	Boolean
camel.hystrix.circuit-breaker-request-volume-threshold	Minimum number of requests in the <code>metricsRollingStatisticalWindowInMilliseconds()</code> that must exist before the <code>HystrixCircuitBreaker</code> will trip. If below this number the circuit will not trip regardless of error percentage.	20	Integer
camel.hystrix.circuit-breaker-sleep-window-in-milliseconds	The time in milliseconds after a <code>HystrixCircuitBreaker</code> trips open that it should wait before trying requests again.	5000	Integer
camel.hystrix.configurations	Define additional configuration definitions.		Map
camel.hystrix.core-pool-size	Core thread-pool size that gets passed to <code>java.util.concurrent.ThreadPoolExecutor#setCorePoolSize(int)</code> .	10	Integer
camel.hystrix.enabled	Enable the component.	true	Boolean
camel.hystrix.execution-isolation-semaphore-max-concurrent-requests	Number of concurrent requests permitted to <code>HystrixCommand.run()</code> . Requests beyond the concurrent limit will be rejected. Applicable only when <code>executionIsolationStrategy == SEMAPHORE</code> .	20	Integer
camel.hystrix.execution-isolation-strategy	What isolation strategy <code>HystrixCommand.run()</code> will be executed with. If <code>THREAD</code> then it will be executed on a separate thread and concurrent requests limited by the number of threads in the thread-pool. If <code>SEMAPHORE</code> then it will be executed on the calling thread and concurrent requests limited by the semaphore count.	THREAD	String

Name	Description	Default	Type
camel.hystrix.execution-isolation-thread-interrupt-on-timeout	Whether the execution thread should attempt an interrupt (using <code>Future#cancel()</code>) when a thread times out. Applicable only when <code>executionIsolationStrategy() == THREAD</code> .	true	Boolean
camel.hystrix.execution-timeout-enabled	Whether the timeout mechanism is enabled for this command.	true	Boolean
camel.hystrix.execution-timeout-in-milliseconds	Time in milliseconds at which point the command will timeout and halt execution. If <code>executionIsolationThreadInterruptOnTimeout == true</code> and the command is thread-isolated, the executing thread will be interrupted. If the command is semaphore-isolated and a <code>HystrixObservableCommand</code> , that command will get unsubscribed.	1000	Integer
camel.hystrix.fallback-enabled	Whether <code>HystrixCommand.getFallback()</code> should be attempted when failure occurs.	true	Boolean
camel.hystrix.fallback-isolation-semaphore-max-concurrent-requests	Number of concurrent requests permitted to <code>HystrixCommand.getFallback()</code> . Requests beyond the concurrent limit will fail-fast and not attempt retrieving a fallback.	10	Integer
camel.hystrix.group-key	Sets the group key to use. The default value is <code>CamelHystrix</code> .	CamelHystrix	String
camel.hystrix.keep-alive-time	Keep-alive time in minutes that gets passed to <code>ThreadPoolExecutor#setKeepAliveTime(long, TimeUnit)</code> .	1	Integer
camel.hystrix.max-queue-size	Max queue size that gets passed to <code>BlockingQueue</code> in <code>HystrixConcurrencyStrategy.getBlockingQueue(int)</code> . This should only affect the instantiation of a threadpool - it is not eligible to change a queue size on the fly. For that, use <code>queueSizeRejectionThreshold()</code> .	-1	Integer
camel.hystrix.maximum-size	Maximum thread-pool size that gets passed to <code>ThreadPoolExecutor#setMaximumPoolSize(int)</code> . This is the maximum amount of concurrency that can be supported without starting to reject <code>HystrixCommands</code> . Please note that this setting only takes effect if you also set <code>allowMaximumSizeToDivergeFromCoreSize</code> .	10	Integer

Name	Description	Default	Type
camel.hystrix.metrics-health-snapshot-interval-in-milliseconds	Time in milliseconds to wait between allowing health snapshots to be taken that calculate success and error percentages and affect <code>HystrixCircuitBreaker.isOpen()</code> status. On high-volume circuits the continual calculation of error percentage can become CPU intensive thus this controls how often it is calculated.	500	Integer
camel.hystrix.metrics-rolling-percentile-bucket-size	Maximum number of values stored in each bucket of the rolling percentile. This is passed into <code>HystrixRollingPercentile</code> inside <code>HystrixCommandMetrics</code> .	10	Integer
camel.hystrix.metrics-rolling-percentile-enabled	Whether percentile metrics should be captured using <code>HystrixRollingPercentile</code> inside <code>HystrixCommandMetrics</code> .	true	Boolean
camel.hystrix.metrics-rolling-percentile-window-buckets	Number of buckets the rolling percentile window is broken into. This is passed into <code>HystrixRollingPercentile</code> inside <code>HystrixCommandMetrics</code> .	6	Integer
camel.hystrix.metrics-rolling-percentile-window-in-milliseconds	Duration of percentile rolling window in milliseconds. This is passed into <code>HystrixRollingPercentile</code> inside <code>HystrixCommandMetrics</code> .	10000	Integer
camel.hystrix.metrics-rolling-statistical-window-buckets	Number of buckets the rolling statistical window is broken into. This is passed into <code>HystrixRollingNumber</code> inside <code>HystrixCommandMetrics</code> .	10	Integer
camel.hystrix.metrics-rolling-statistical-window-in-milliseconds	This property sets the duration of the statistical rolling window, in milliseconds. This is how long metrics are kept for the thread pool. The window is divided into buckets and rolls by those increments.	10000	Integer
camel.hystrix.queue-size-rejection-threshold	Queue size rejection threshold is an artificial max size at which rejections will occur even if <code>maxQueueSize</code> has not been reached. This is done because the <code>maxQueueSize</code> of a <code>BlockingQueue</code> can not be dynamically changed and we want to support dynamically changing the queue size that affects rejections. This is used by <code>HystrixCommand</code> when queuing a thread for execution.	5	Integer

Name	Description	Default	Type
<code>camel.hystrix.request-log-enabled</code>	Whether HystrixCommand execution and events should be logged to HystrixRequestLog.	true	Boolean
<code>camel.hystrix.thread-pool-key</code>	Sets the thread pool key to use. Will by default use the same value as groupKey has been configured to use.	Camel Hystrix	String
<code>camel.hystrix.thread-pool-rolling-number-statistical-window-buckets</code>	Number of buckets the rolling statistical window is broken into. This is passed into HystrixRollingNumber inside each HystrixThreadPoolMetrics instance.	10	Integer
<code>camel.hystrix.thread-pool-rolling-number-statistical-window-in-milliseconds</code>	Duration of statistical rolling window in milliseconds. This is passed into HystrixRollingNumber inside each HystrixThreadPoolMetrics instance.	10000	Integer
<code>camel.language.constant.enabled</code>	Whether to enable auto configuration of the constant language. This is enabled by default.		Boolean
<code>camel.language.constant.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
<code>camel.language.csimple.enabled</code>	Whether to enable auto configuration of the csimple language. This is enabled by default.		Boolean
<code>camel.language.csimple.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
<code>camel.language.exchangeproperty.enabled</code>	Whether to enable auto configuration of the exchangeProperty language. This is enabled by default.		Boolean
<code>camel.language.exchangeproperty.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
<code>camel.language.file.enabled</code>	Whether to enable auto configuration of the file language. This is enabled by default.		Boolean
<code>camel.language.file.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean

Name	Description	Default	Type
<code>camel.language.header.enabled</code>	Whether to enable auto configuration of the header language. This is enabled by default.		Boolean
<code>camel.language.header.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
<code>camel.language.ref.enabled</code>	Whether to enable auto configuration of the ref language. This is enabled by default.		Boolean
<code>camel.language.ref.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
<code>camel.language.simple.enabled</code>	Whether to enable auto configuration of the simple language. This is enabled by default.		Boolean
<code>camel.language.simple.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
<code>camel.language.tokenize.enabled</code>	Whether to enable auto configuration of the tokenize language. This is enabled by default.		Boolean
<code>camel.language.tokenize.group-delimiter</code>	Sets the delimiter to use when grouping. If this has not been set then token will be used as the delimiter.		String
<code>camel.language.tokenize.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
<code>camel.resilience4j.automatic-transition-from-open-to-half-open-enabled</code>	Enables automatic transition from OPEN to HALF_OPEN state once the <code>waitDurationInOpenState</code> has passed.	false	Boolean
<code>camel.resilience4j.circuit-breaker-ref</code>	Refers to an existing <code>io.github.resilience4j.circuitbreaker.CircuitBreaker</code> instance to lookup and use from the registry. When using this, then any other circuit breaker options are not in use.		String
<code>camel.resilience4j.config-ref</code>	Refers to an existing <code>io.github.resilience4j.circuitbreaker.CircuitBreakerConfig</code> instance to lookup and use from the registry.		String
<code>camel.resilience4j.configurations</code>	Define additional configuration definitions.		Map

Name	Description	Default	Type
camel.resilience4j.enabled	Enable the component.	true	Boolean
camel.resilience4j.failure-rate-threshold	Configures the failure rate threshold in percentage. If the failure rate is equal or greater than the threshold the CircuitBreaker transitions to open and starts short-circuiting calls. The threshold must be greater than 0 and not greater than 100. Default value is 50 percentage.		Float
camel.resilience4j.minimum-number-of-calls	Configures the minimum number of calls which are required (per sliding window period) before the CircuitBreaker can calculate the error rate. For example, if minimumNumberOfCalls is 10, then at least 10 calls must be recorded, before the failure rate can be calculated. If only 9 calls have been recorded the CircuitBreaker will not transition to open even if all 9 calls have failed. Default minimumNumberOfCalls is 100.	100	Integer
camel.resilience4j.permitted-number-of-calls-in-half-open-state	Configures the number of permitted calls when the CircuitBreaker is half open. The size must be greater than 0. Default size is 10.	10	Integer
camel.resilience4j.sliding-window-size	Configures the size of the sliding window which is used to record the outcome of calls when the CircuitBreaker is closed. slidingWindowSize configures the size of the sliding window. Sliding window can either be count-based or time-based. If slidingWindowType is COUNT_BASED, the last slidingWindowSize calls are recorded and aggregated. If slidingWindowType is TIME_BASED, the calls of the last slidingWindowSize seconds are recorded and aggregated. The slidingWindowSize must be greater than 0. The minimumNumberOfCalls must be greater than 0. If the slidingWindowType is COUNT_BASED, the minimumNumberOfCalls cannot be greater than slidingWindowSize . If the slidingWindowType is TIME_BASED, you can pick whatever you want. Default slidingWindowSize is 100.	100	Integer

Name	Description	Default	Type
camel.resilience4j.sliding-window-type	Configures the type of the sliding window which is used to record the outcome of calls when the CircuitBreaker is closed. Sliding window can either be count-based or time-based. If slidingWindowType is COUNT_BASED, the last slidingWindowSize calls are recorded and aggregated. If slidingWindowType is TIME_BASED, the calls of the last slidingWindowSize seconds are recorded and aggregated. Default slidingWindowType is COUNT_BASED.	COUNT_BASED	String
camel.resilience4j.slow-call-duration-threshold	Configures the duration threshold (seconds) above which calls are considered as slow and increase the slow calls percentage. Default value is 60 seconds.	60	Integer
camel.resilience4j.slow-call-rate-threshold	Configures a threshold in percentage. The CircuitBreaker considers a call as slow when the call duration is greater than slowCallDurationThreshold Duration. When the percentage of slow calls is equal or greater the threshold, the CircuitBreaker transitions to open and starts short-circuiting calls. The threshold must be greater than 0 and not greater than 100. Default value is 100 percentage which means that all recorded calls must be slower than slowCallDurationThreshold.		Float
camel.resilience4j.wait-duration-in-open-state	Configures the wait duration (in seconds) which specifies how long the CircuitBreaker should stay open, before it switches to half open. Default value is 60 seconds.	60	Integer
camel.resilience4j.writable-stack-trace-enabled	Enables writable stack traces. When set to false, Exception.getStackTrace returns a zero length array. This may be used to reduce log spam when the circuit breaker is open as the cause of the exceptions is already known (the circuit breaker is short-circuiting calls).	true	Boolean
camel.rest.api-component	The name of the Camel component to use as the REST API (such as swagger) If no API Component has been explicit configured, then Camel will lookup if there is a Camel component responsible for servicing and generating the REST API documentation, or if a org.apache.camel.spi.RestApiProcessorFactory is registered in the registry. If either one is found, then that is being used.		String

Name	Description	Default	Type
camel.rest.api-context-path	Sets a leading API context-path the REST API services will be using. This can be used when using components such as camel-servlet where the deployed web application is deployed using a context-path.		String
camel.rest.api-context-route-id	Sets the route id to use for the route that services the REST API. The route will by default use an auto assigned route id.		String
camel.rest.api-host	To use an specific hostname for the API documentation (eg swagger) This can be used to override the generated host with this configured hostname.		String
camel.rest.api-property	Allows to configure as many additional properties for the api documentation (swagger). For example set property api.title to my cool stuff.		Map
camel.rest.api-vendor-extension	Whether vendor extension is enabled in the Rest APIs. If enabled then Camel will include additional information as vendor extension (eg keys starting with x-) such as route ids, class names etc. Not all 3rd party API gateways and tools supports vendor-extensions when importing your API docs.	false	Boolean
camel.rest.binding-mode	Sets the binding mode to use. The default value is off.		RestBindingMode
camel.rest.client-request-validation	Whether to enable validation of the client request to check whether the Content-Type and Accept headers from the client is supported by the Rest-DSL configuration of its consumes/produces settings. This can be turned on, to enable this check. In case of validation error, then HTTP Status codes 415 or 406 is returned. The default value is false.	false	Boolean
camel.rest.component	The Camel Rest component to use for the REST transport (consumer), such as netty-http, jetty, servlet, undertow. If no component has been explicit configured, then Camel will lookup if there is a Camel component that integrates with the Rest DSL, or if a org.apache.camel.spi.RestConsumerFactory is registered in the registry. If either one is found, then that is being used.		String

Name	Description	Default	Type
camel.rest.component-property	Allows to configure as many additional properties for the rest component in use.		Map
camel.rest.consumer-property	Allows to configure as many additional properties for the rest consumer in use.		Map
camel.rest.context-path	Sets a leading context-path the REST services will be using. This can be used when using components such as camel-servlet where the deployed web application is deployed using a context-path. Or for components such as camel-jetty or camel-netty-http that includes a HTTP server.		String
camel.rest.cors-headers	Allows to configure custom CORS headers.		Map
camel.rest.data-format-property	Allows to configure as many additional properties for the data formats in use. For example set property prettyPrint to true to have json outputted in pretty mode. The properties can be prefixed to denote the option is only for either JSON or XML and for either the IN or the OUT. The prefixes are: json.in. json.out. xml.in. xml.out. For example a key with value xml.out.mustBeJAXBELEMENT is only for the XML data format for the outgoing. A key without a prefix is a common key for all situations.		Map
camel.rest.enable-cors	Whether to enable CORS headers in the HTTP response. The default value is false.	false	Boolean
camel.rest.endpoint-property	Allows to configure as many additional properties for the rest endpoint in use.		Map
camel.rest.host	The hostname to use for exposing the REST service.		String
camel.rest.host-name-resolver	If no hostname has been explicit configured, then this resolver is used to compute the hostname the REST service will be using.		RestHostNameResolver
camel.rest.json-data-format	Name of specific json data format to use. By default json-jackson will be used. Important: This option is only for setting a custom name of the data format, not to refer to an existing data format instance.		String

Name	Description	Default	Type
camel.rest.port	The port number to use for exposing the REST service. Notice if you use servlet component then the port number configured here does not apply, as the port number in use is the actual port number the servlet component is using. eg if using Apache Tomcat its the tomcat http port, if using Apache Karaf its the HTTP service in Karaf that uses port 8181 by default etc. Though in those situations setting the port number here, allows tooling and JMX to know the port number, so its recommended to set the port number to the number that the servlet engine uses.		String
camel.rest.producer-api-doc	Sets the location of the api document (swagger api) the REST producer will use to validate the REST uri and query parameters are valid accordingly to the api document. This requires adding camel-swagger-java to the classpath, and any miss configuration will let Camel fail on startup and report the error(s). The location of the api document is loaded from classpath by default, but you can use file: or http: to refer to resources to load from file or http url.		String
camel.rest.producer-component	Sets the name of the Camel component to use as the REST producer.		String
camel.rest.scheme	The scheme to use for exposing the REST service. Usually http or https is supported. The default value is http.		String
camel.rest.skip-binding-on-error-code	Whether to skip binding on output if there is a custom HTTP error code header. This allows to build custom error messages that do not bind to json / xml etc, as success messages otherwise will do.	false	Boolean
camel.rest.use-x-forward-headers	Whether to use X-Forward headers for Host and related setting. The default value is true.	true	Boolean
camel.rest.xml-data-format	Name of specific XML data format to use. By default jaxb will be used. Important: This option is only for setting a custom name of the data format, not to refer to an existing data format instance.		String

Name	Description	Default	Type
camel.rest.api-context-id-pattern	Deprecated Sets an CamelContext id pattern to only allow Rest APIs from rest services within CamelContext's which name matches the pattern. The pattern name refers to the CamelContext name, to match on the current CamelContext only. For any other value, the pattern uses the rules from PatternHelper#matchPattern(String,String).		String
camel.rest.api-context-listing	Deprecated Sets whether listing of all available CamelContext's with REST services in the JVM is enabled. If enabled it allows to discover these contexts, if false then only the current CamelContext is in use.	false	Boolean

CHAPTER 39. FLINK

Since Camel 2.18

Only producer is supported

This documentation page covers the [Flink](#) component for the Apache Camel. The **camel-flink** component provides a bridge between Camel components and Flink tasks. This component provides a way to route a message from various transports, dynamically choosing a flink task to execute, use an incoming message as input data for the task and finally deliver the results back to the Camel pipeline.

39.1. DEPENDENCIES

When using **camel-flink** with Red Hat build of Camel Spring Boot, add the following Maven dependency to your **pom.xml** to have support for auto configuration:

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-flink-starter</artifactId>
</dependency>
```

39.2. URI FORMAT

Currently, the Flink Component supports only Producers. One can create DataSet, DataStream jobs.

```
flink:dataset?dataset=#myDataSet&dataSetCallback=#dataSetCallback
flink:datastream?datastream=#myDataStream&dataStreamCallback=#dataStreamCallback
```

39.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

39.3.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).

- directly in the Java code.

39.3.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

39.4. COMPONENT OPTIONS

The Flink component supports 5 options, which are listed below.

Name	Description	Default	Type
dataSetCallback (producer)	Function performing action against a DataSet.		DataSetCallback
dataStream (producer)	DataStream to compute against.		DataStream
dataStreamCallback (producer)	Function performing action against a DataStream.		DataStreamCallback
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

Name	Description	Default	Type
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

39.5. ENDPOINT OPTIONS

The Flink endpoint is configured using URI syntax:

```
flink:endpointType
```

With the following *path* and *query* parameters:

39.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
endpointType (producer)	Required Type of the endpoint (dataset, datastream). Enum values: - dataset - datastream		EndpointType

39.5.2. Query Parameters (6 parameters)

Name	Description	Default	Type
collect (producer)	Indicates if results should be collected or counted.	true	boolean
dataSet (producer)	DataSet to compute against.		DataSet
dataSetCallback (producer)	Function performing action against a DataSet.		DataSetCallback

Name	Description	Default	Type
dataStream (producer)	DataStream to compute against.		DataStream
dataStreamCallback (producer)	Function performing action against a DataStream.		DataStreamCallback
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

39.6. MESSAGE HEADERS

The Flink component supports 4 message header(s), which is/are listed below:

Name	Description	Default	Type
CamelFlinkDataSet (producer) Constant: FLINK_DATASET_HEADER	The dataset.		Object
CamelFlinkDataSetCallback (producer) Constant: FLINK_DATASET_CALLBACK_HEADER	The dataset callback.		DataSetCallback
CamelFlinkDataStream (producer) Constant: FLINK_DATASTREAM_HEADER	The data stream.		Object

Name	Description	Default	Type
CamelFlinkDataStreamCallback (producer) Constant: FLINK_DATASTREAM_CALLBACK_HEADER	The data stream callback.		DataStreamCallback

39.7. FLINK DATASET CALLBACK

```

@Bean
public DataSetCallback<Long> dataSetCallback() {
    return new DataSetCallback<Long>() {
        public Long onDataSet(DataSet dataSet, Object... objects) {
            try {
                dataSet.print();
                return new Long(0);
            } catch (Exception e) {
                return new Long(-1);
            }
        }
    };
}

```

39.8. FLINK DATASTREAM CALLBACK

```

@Bean
public VoidDataStreamCallback dataStreamCallback() {
    return new VoidDataStreamCallback() {
        @Override
        public void doOnDataStream(DataStream dataStream, Object... objects) throws Exception {
            dataStream.flatMap(new Splitter()).print();

            environment.execute("data stream test");
        }
    };
}

```

39.9. CAMEL-FLINK PRODUCER CALL

```

CamelContext camelContext = new SpringCamelContext(context);

String pattern = "foo";

try {
    ProducerTemplate template = camelContext.createProducerTemplate();
    camelContext.start();
    Long count = template.requestBody("flink:dataSet?

```

```

dataSet=#myDataSet&dataSetCallback=#countLinesContaining", pattern, Long.class);
    } finally {
        camelContext.stop();
    }
}

```

39.10. SPRING BOOT AUTO-CONFIGURATION

The component supports 6 options, which are listed below.

Name	Description	Default	Type
camel.component.flink.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.flink.data-set-callback	Function performing action against a DataSet. The option is a <code>org.apache.camel.component.flink.DataSetCallback</code> type.		DataSetCallback
camel.component.flink.data-stream	DataStream to compute against. The option is a <code>org.apache.flink.streaming.api.datastream.DataStream</code> type.		DataStream
camel.component.flink.data-stream-callback	Function performing action against a DataStream. The option is a <code>org.apache.camel.component.flink.DataStreamCallback</code> type.		DataStreamCallback
camel.component.flink.enabled	Whether to enable auto configuration of the flink component. This is enabled by default.		Boolean
camel.component.flink.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 40. FTP

Both producer and consumer are supported

This component provides access to remote file systems over the FTP and SFTP protocols.

When consuming from remote FTP server make sure you read the section titled *Default when consuming files* further below for details related to consuming files.

Absolute path is **not** supported. Camel translates absolute path to relative by trimming all leading slashes from **directoryname**. There'll be WARN message printed in the logs.

40.1. DEPENDENCIES

When using **ftp** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-ftp-starter</artifactId>
</dependency>
```

40.2. URI FORMAT

```
ftp://[username@]hostname[:port]/directoryname[?options]
sftp://[username@]hostname[:port]/directoryname[?options]
ftps://[username@]hostname[:port]/directoryname[?options]
```

Where **directoryname** represents the underlying directory. The directory name is a relative path. Absolute path's is **not** supported. The relative path can contain nested folders, such as /inbox/us.

The **autoCreate** option is supported. When consumer starts, before polling is scheduled, there's additional FTP operation performed to create the directory configured for endpoint. The default value for **autoCreate** is **true**.

If no **username** is provided, then **anonymous** login is attempted using no password.

If no **port** number is provided, Camel will provide default values according to the protocol (ftp = 21, sftp = 22, ftps = 2222).

You can append query options to the URI in the following format, **?option=value&option=value&...**

This component uses two different libraries for the actual FTP work. FTP and FTPS uses [Apache Commons Net](#) while SFTP uses [JCraft JSCH](#).

FTPS (also known as FTP Secure) is an extension to FTP that adds support for the Transport Layer Security (TLS) and the Secure Sockets Layer (SSL) cryptographic protocols.

40.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level

- endpoint level

40.3.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).
- directly in the Java code.

40.3.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

40.4. COMPONENT OPTIONS

The FTP component supports 3 options, which are listed below.

Name	Description	Default	Type
		t	

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

40.5. ENDPOINT OPTIONS

The FTP endpoint is configured using URI syntax:

```
ftp:host:port/directoryName
```

with the following path and query parameters:

40.5.1. Path Parameters (3 parameters)

Name	Description	Default	Type
host (common)	Required Hostname of the FTP server.		String
port (common)	Port of the FTP server.		int

Name	Description	Default	Type
directoryName (common)	The starting directory.		String

40.5.2. Query Parameters (111 parameters)

Name	Description	Default	Type
binary (common)	Specifies the file transfer mode, BINARY or ASCII. Default is ASCII (false).	false	boolean
charset (common)	This option is used to specify the encoding of the file. You can use this on the consumer, to specify the encodings of the files, which allow Camel to know the charset it should load the file content in case the file content is being accessed. Likewise when writing a file, you can use this option to specify which charset to write the file as well. Do mind that when writing the file Camel may have to read the message content into memory to be able to convert the data into the configured charset, so do not use this if you have big messages.		String
disconnect (common)	Whether or not to disconnect from remote FTP server right after use. Disconnect will only disconnect the current connection to the FTP server. If you have a consumer which you want to stop, then you need to stop the consumer/route instead.	false	boolean
doneFileName (common)	Producer: If provided, then Camel will write a 2nd done file when the original file has been written. The done file will be empty. This option configures what file name to use. Either you can specify a fixed name. Or you can use dynamic placeholders. The done file will always be written in the same folder as the original file. Consumer: If provided, Camel will only consume files if a done file exists. This option configures what file name to use. Either you can specify a fixed name. Or you can use dynamic placeholders. The done file is always expected in the same folder as the original file. Only <code>\${file.name}</code> and <code>\${file.name.next}</code> is supported as dynamic placeholders.		String

Name	Description	Default	Type
fileName (common)	Use Expression such as File Language to dynamically set the filename. For consumers, it's used as a filename filter. For producers, it's used to evaluate the filename to write. If an expression is set, it take precedence over the CamelFileName header. (Note: The header itself can also be an Expression). The expression options support both String and Expression types. If the expression is a String type, it is always evaluated using the File Language. If the expression is an Expression type, the specified Expression type is used - this allows you, for instance, to use OGNL expressions. For the consumer, you can use it to filter filenames, so you can for instance consume today's file using the File Language syntax: mydata-\${date:now:yyyyMMdd}.txt. The producers support the CamelOverrideFileName header which takes precedence over any existing CamelFileName header; the CamelOverrideFileName is a header that is used only once, and makes it easier as this avoids to temporary store CamelFileName and have to restore it afterwards.		String
passiveMode (common)	Sets passive mode connections. Default is active mode connections.	false	boolean
separator (common)	Sets the path separator to be used. UNIX = Uses unix style path separator Windows = Uses windows style path separator Auto = (is default) Use existing path separator in file name. Enum values: • UNIX • Windows • Auto	UNIX	PathSeparator
transferLoggingIntervalSeconds (common)	Configures the interval in seconds to use when logging the progress of upload and download operations that are in-flight. This is used for logging progress when operations takes longer time.	5	int

Name	Description	Default	Type
transferLoggingLevel (common)	Configure the logging level to use when logging the progress of upload and download operations. Enum values: ● TRACE ● DEBUG ● INFO ● WARN ● ERROR ● OFF	DEBUG	LogLevel
transferLoggingVerbose (common)	Configures whether the perform verbose (fine grained) logging of the progress of upload and download operations.	false	boolean
fastExistsCheck (common (advanced))	If set this option to be true, camel-ftp will use the list file directly to check if the file exists. Since some FTP server may not support to list the file directly, if the option is false, camel-ftp will use the old way to list the directory and check if the file exists. This option also influences readLock=changed to control whether it performs a fast check to update file information or not. This can be used to speed up the process if the FTP server has a lot of files.	false	boolean
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
delete (consumer)	If true, the file will be deleted after it is processed successfully.	false	boolean
moveFailed (consumer)	Sets the move failure expression based on Simple language. For example, to move files into a .error subdirectory use: .error. Note: When moving the files to the fail location Camel will handle the error and will not pick up the file again.		String

Name	Description	Default	Type
noop (consumer)	If true, the file is not moved or deleted in any way. This option is good for readonly data, or for ETL type requirements. If noop=true, Camel will set idempotent=true as well, to avoid consuming the same files over and over again.	false	boolean
preMove (consumer)	Expression (such as File Language) used to dynamically set the filename when moving it before processing. For example to move in-progress files into the order directory set this value to order.		String
preSort (consumer)	When pre-sort is enabled then the consumer will sort the file and directory names during polling, that was retrieved from the file system. You may want to do this in case you need to operate on the files in a sorted order. The pre-sort is executed before the consumer starts to filter, and accept files to process by Camel. This option is default=false meaning disabled.	false	boolean
recursive (consumer)	If a directory, will look for files in all the sub-directories as well.	false	boolean
resumeDownload (consumer)	Configures whether resume download is enabled. This must be supported by the FTP server (almost all FTP servers support it). In addition the options localWorkDirectory must be configured so downloaded files are stored in a local directory, and the option binary must be enabled, which is required to support resuming of downloads.	false	boolean
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean
streamDownload (consumer)	Sets the download method to use when not using a local working directory. If set to true, the remote files are streamed to the route as they are read. When set to false, the remote files are loaded into memory before being sent into the route. If enabling this option then you must set stepwise=false as both cannot be enabled at the same time.	false	boolean
download (consumer (advanced))	Whether the FTP consumer should download the file. If this option is set to false, then the message body will be null, but the consumer will still trigger a Camel Exchange that has details about the file such as file name, file size, etc. It's just that the file will not be downloaded.	false	boolean

Name	Description	Default	Type
exceptionHandler (consumer (advanced))	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at <code>WARN</code> or <code>ERROR</code> level and ignored.		<code>ExceptionHandler</code>
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • <code>InOnly</code> • <code>InOut</code> • <code>InOptionalOut</code>		<code>ExchangePattern</code>
handleDirectoryParserAbsoluteResult (consumer (advanced))	Allows you to set how the consumer will handle subfolders and files in the path if the directory parser results in with absolute paths. The reason for this is that some FTP servers may return file names with absolute paths, and if so then the FTP component needs to handle this by converting the returned path into a relative path.	<code>false</code>	<code>boolean</code>
ignoreFileNotFoundOrPermissionError (consumer (advanced))	Whether to ignore when (trying to list files in directories or when downloading a file), which does not exist or due to permission error. By default when a directory or file does not exist or insufficient permission, then an exception is thrown. Setting this option to <code>true</code> allows to ignore that instead.	<code>false</code>	<code>boolean</code>
inProgressRepository (consumer (advanced))	A pluggable in-progress repository <code>org.apache.camel.spi.IdempotentRepository</code> . The in-progress repository is used to account the current in progress files being consumed. By default a memory based repository is used.		<code>IdempotentRepository</code>
localWorkDirectory (consumer (advanced))	When consuming, a local work directory can be used to store the remote file content directly in local files, to avoid loading the content into memory. This is beneficial, if you consume a very big remote file and thus can conserve memory.		<code>String</code>

Name	Description	Default	Type
onCompletionExceptionHandler (consumer (advanced))	To use a custom <code>org.apache.camel.spi.ExceptionHandler</code> to handle any thrown exceptions that happens during the file on completion process where the consumer does either a commit or rollback. The default implementation will log any exception at WARN level and ignore.		ExceptionHandler
pollStrategy (consumer (advanced))	A pluggable <code>org.apache.camel.PollingConsumerPollingStrategy</code> allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		PollingConsumerPollStrategy
processStrategy (consumer (advanced))	A pluggable <code>org.apache.camel.component.file.GenericFileProcessStrategy</code> allowing you to implement your own <code>readLock</code> option or similar. Can also be used when special conditions must be met before a file can be consumed, such as a special ready file exists. If this option is set then the <code>readLock</code> option does not apply.		GenericFileProcessStrategy
useList (consumer (advanced))	Whether to allow using LIST command when downloading a file. Default is true. In some use cases you may want to download a specific file and are not allowed to use the LIST command, and therefore you can set this option to false. Notice when using this option, then the specific file to download does not include meta-data information such as file size, timestamp, permissions etc, because those information is only possible to retrieve when LIST command is in use.	true	boolean

Name	Description	Default	Type
fileExist (producer)	What to do if a file already exists with the same name. Override, which is the default, replaces the existing file. – Append – adds content to the existing file. – Fail – throws a <code>GenericFileOperationException</code>, indicating that there is already an existing file. – Ignore – silently ignores the problem and does not override the existing file, but assumes everything is okay. – Move – option requires to use the <code>moveExisting</code> option to be configured as well. The option <code>eagerDeleteTargetFile</code> can be used to control what to do if an moving the file, and there exists already an existing file, otherwise causing the move operation to fail. The Move option will move any existing files, before writing the target file. – TryRename is only applicable if <code>tempFileName</code> option is in use. This allows to try renaming the file from the temporary name to the actual name, without doing any exists check. This check may be faster on some file systems and especially FTP servers. Enum values: • Override • Append • Fail • Ignore • Move • TryRename	Override	GenericFileExist
flatten (producer)	Flatten is used to flatten the file name path to strip any leading paths, so it's just the file name. This allows you to consume recursively into sub-directories, but when you eg write the files to another directory they will be written in a single directory. Setting this to true on the producer enforces that any file name in <code>CamelFileName</code> header will be stripped for any leading paths.	false	boolean
jailStartingDirectory (producer)	Used for jailing (restricting) writing files to the starting directory (and sub) only. This is enabled by default to not allow Camel to write files to outside directories (to be more secured out of the box). You can turn this off to allow writing files to directories outside the starting directory, such as parent or root folders.	true	boolean

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
moveExisting (producer)	Expression (such as File Language) used to compute file name to use when fileExist=Move is configured. To move files into a backup subdirectory just enter backup. This option only supports the following File Language tokens: file:name, file:name.ext, file:name.noext, file:onlyname, file:onlyname.noext, file:ext, and file:parent. Notice the file:parent is not supported by the FTP component, as the FTP component can only move any existing files to a relative directory based on current dir as base.		String
tempFileName (producer)	The same as tempPrefix option but offering a more fine grained control on the naming of the temporary filename as it uses the File Language. The location for tempFileName is relative to the final file location in the option 'fileName', not the target directory in the base uri. For example if option fileName includes a directory prefix: dir/finalFilename then tempFileName is relative to that subdirectory dir.		String
tempPrefix (producer)	This option is used to write the file using a temporary name and then, after the write is complete, rename it to the real name. Can be used to identify files being written and also avoid consumers (not using exclusive read locks) reading in progress files. Is often used by FTP when uploading big files.		String
allowNullBody (producer (advanced))	Used to specify if a null body is allowed during file writing. If set to true then an empty file will be created, when set to false, and attempting to send a null body to the file component, a GenericFileWriteException of 'Cannot write null body to file.' will be thrown. If the fileExist option is set to 'Override', then the file will be truncated, and if set to append the file will remain unchanged.	false	boolean

Name	Description	Default	Type
chmod (producer (advanced))	Allows you to set chmod on the stored file. For example chmod=640.		String
disconnectOnBatchComplete (producer (advanced))	Whether or not to disconnect from remote FTP server right after a Batch upload is complete. disconnectOnBatchComplete will only disconnect the current connection to the FTP server.	false	boolean
eagerDeleteTargetFile (producer (advanced))	Whether or not to eagerly delete any existing target file. This option only applies when you use fileExists=Override and the tempFileName option as well. You can use this to disable (set it to false) deleting the target file before the temp file is written. For example you may write big files and want the target file to exist during the temp file is being written. This ensures the target file is only deleted until the very last moment, just before the temp file is being renamed to the target filename. This option is also used to control whether to delete any existing files when fileExist=Move is enabled, and an existing file exists. If this option copyAndDeleteOnRenameFails false, then an exception will be thrown if an existing file existed, if its true, then the existing file is deleted before the move operation.	true	boolean
keepLastModified (producer (advanced))	Will keep the last modified timestamp from the source file (if any). Will use the Exchange.FILE_LAST_MODIFIED header to locate the timestamp. This header can contain either a java.util.Date or long with the timestamp. If the timestamp exists and the option is enabled it will set this timestamp on the written file. Note: This option only applies to the file producer. You cannot use this option with any of the ftp producers.	false	boolean
moveExistingFileStrategy (producer (advanced))	Strategy (Custom Strategy) used to move file with special naming token to use when fileExist=Move is configured. By default, there is an implementation used if no custom strategy is provided.		FileMoveExistingStrategy
sendNoop (producer (advanced))	Whether to send a noop command as a pre-write check before uploading files to the FTP server. This is enabled by default as a validation of the connection is still valid, which allows to silently re-connect to be able to upload the file. However if this causes problems, you can turn this option off.	true	boolean

Name	Description	Default	Type
activePortRange (advanced)	Set the client side port range in active mode. The syntax is: minPort-maxPort Both port numbers are inclusive, eg 10000-19999 to include all lxxxx ports.		String
autoCreate (advanced)	Automatically create missing directories in the file's pathname. For the file consumer, that means creating the starting directory. For the file producer, it means the directory the files should be written to.	true	boolean
bufferSize (advanced)	Buffer size in bytes used for writing files (or in case of FTP for downloading and uploading files).	131072	int
connectTimeout (advanced)	Sets the connect timeout for waiting for a connection to be established Used by both FTPClient and JSCH.	10000	int
ftpClient (advanced)	To use a custom instance of FTPClient.		FTPClient
ftpClientConfig (advanced)	To use a custom instance of FTPClientConfig to configure the FTP client the endpoint should use.		FTPClientConfig
ftpClientConfigParameters (advanced)	Used by FtpComponent to provide additional parameters for the FTPClientConfig.		Map
ftpClientParameters (advanced)	Used by FtpComponent to provide additional parameters for the FTPClient.		Map
maximumReconnectAttempts (advanced)	Specifies the maximum reconnect attempts Camel performs when it tries to connect to the remote FTP server. Use 0 to disable this behavior.		int
reconnectDelay (advanced)	Delay in millis Camel will wait before performing a reconnect attempt.	1000	long
siteCommand (advanced)	Sets optional site command(s) to be executed after successful login. Multiple site commands can be separated using a new line character.		String
soTimeout (advanced)	Sets the so timeout FTP and FTPS Is the SocketOptions.SO_TIMEOUT value in millis. Recommended option is to set this to 300000 so as not have a hanged connection. On SFTP this option is set as timeout on the JSCH Session instance.	300000	int

Name	Description	Default	Type
stepwise (advanced)	Sets whether we should stepwise change directories while traversing file structures when downloading files, or as well when uploading a file to a directory. You can disable this if you for example are in a situation where you cannot change directory on the FTP server due security reasons. Stepwise cannot be used together with streamDownload.	true	boolean
synchronous (advanced)	Sets whether synchronous processing should be strictly used.	false	boolean
throwExceptionOnConnectFailed (advanced)	Should an exception be thrown if connection failed (exhausted)By default exception is not thrown and a WARN is logged. You can use this to enable exception being thrown and handle the thrown exception from the org.apache.camel.spi.PollingConsumerPollStrategy rollback method.	false	boolean
timeout (advanced)	Sets the data timeout for waiting for reply Used only by FTPClient.	30000	int
antExclude (filter)	Ant style filter exclusion. If both antInclude and antExclude are used, antExclude takes precedence over antInclude. Multiple exclusions may be specified in comma-delimited format.		String
antFilterCaseSensitive (filter)	Sets case sensitive flag on ant filter.	true	boolean
antInclude (filter)	Ant style filter inclusion. Multiple inclusions may be specified in comma-delimited format.		String
eagerMaxMessagesPerPoll (filter)	Allows for controlling whether the limit from maxMessagesPerPoll is eager or not. If eager then the limit is during the scanning of files. Where as false would scan all files, and then perform sorting. Setting this option to false allows for sorting all files first, and then limit the poll. Mind that this requires a higher memory usage as all file details are in memory to perform the sorting.	true	boolean
exclude (filter)	Is used to exclude files, if filename matches the regex pattern (matching is case in-sensitive). Notice if you use symbols such as plus sign and others you would need to configure this using the RAW() syntax if configuring this as an endpoint uri. See more details at configuring endpoint uris.		String

Name	Description	Default	Type
excludeExt (filter)	Is used to exclude files matching file extension name (case insensitive). For example to exclude bak files, then use excludeExt=bak. Multiple extensions can be separated by comma, for example to exclude bak and dat files, use excludeExt=bak,dat. Note that the file extension includes all parts, for example having a file named mydata.tar.gz will have extension as tar.gz. For more flexibility then use the include/exclude options.		String
filter (filter)	Pluggable filter as a org.apache.camel.component.file.GenericFileFilter class. Will skip files if filter returns false in its accept() method.		GenericFileFilter
filterDirectory (filter)	Filters the directory based on Simple language. For example to filter on current date, you can use a simple date pattern such as <code>\$\$\{date:now:yyyMMdd}</code> .		String
filterFile (filter)	Filters the file based on Simple language. For example to filter on file size, you can use <code>\$\$\{file:size} 5000</code> .		String
idempotent (filter)	Option to use the Idempotent Consumer EIP pattern to let Camel skip already processed files. Will by default use a memory based LRUCache that holds 1000 entries. If noop=true then idempotent will be enabled as well to avoid consuming the same files over and over again.	false	Boolean
idempotentKey (filter)	To use a custom idempotent key. By default the absolute path of the file is used. You can use the File Language, for example to use the file name and file size, you can do: idempotentKey= <code>\$\$\{file:name}-\$\$\{file:size}</code> .		String
idempotentRepository (filter)	A pluggable repository org.apache.camel.spi.IdempotentRepository which by default use MemoryIdempotentRepository if none is specified and idempotent is true.		IdempotentRepository

Name	Description	Default	Type
include (filter)	Is used to include files, if filename matches the regex pattern (matching is case in-sensitive). Notice if you use symbols such as plus sign and others you would need to configure this using the RAW() syntax if configuring this as an endpoint uri. See more details at configuring endpoint uris.		String
includeExt (filter)	Is used to include files matching file extension name (case insensitive). For example to include txt files, then use includeExt=txt. Multiple extensions can be separated by comma, for example to include txt and xml files, use includeExt=txt,xml. Note that the file extension includes all parts, for example having a file named mydata.tar.gz will have extension as tar.gz. For more flexibility then use the include/exclude options.		String
maxDepth (filter)	The maximum depth to traverse when recursively processing a directory.	2147483647	int
maxMessagesPerPoll (filter)	To define a maximum messages to gather per poll. By default no maximum is set. Can be used to set a limit of e.g. 1000 to avoid when starting up the server that there are thousands of files. Set a value of 0 or negative to disabled it. Notice: If this option is in use then the File and FTP components will limit before any sorting. For example if you have 100000 files and use maxMessagesPerPoll=500, then only the first 500 files will be picked up, and then sorted. You can use the eagerMaxMessagesPerPoll option and set this to false to allow to scan all files first and then sort afterwards.		int
minDepth (filter)	The minimum depth to start processing when recursively processing a directory. Using minDepth=1 means the base directory. Using minDepth=2 means the first sub directory.		int
move (filter)	Expression (such as Simple Language) used to dynamically set the filename when moving it after processing. To move files into a .done subdirectory just enter .done.		String
exclusiveReadLockStrategy (lock)	Pluggable read-lock as a org.apache.camel.component.file.GenericFileExclusiveReadLockStrategy implementation.		GenericFileExclusiveReadLockStrategy

readLock (lock) Name	Description	none Default	String Type
	Used by consumer, to only poll the files if it has exclusive read-lock on the file (i.e. the file is not in-progress or being written). Camel will wait until the file lock is granted. This option provides the build in strategies: - none - No read lock is in use - markerFile - Camel creates a marker file (fileName.camellLock) and then holds a lock on it. This option is not available for the FTP component - changed - Changed is using file length/modification timestamp to detect whether the file is currently being copied or not. Will at least use 1 sec to determine this, so this option cannot consume files as fast as the others, but can be more reliable as the JDK IO API cannot always determine whether a file is currently being used by another process. The option readLockCheckInterval can be used to set the check frequency. - fileLock - is for using java.nio.channels.FileLock. This option is not avail for Windows OS and the FTP component. This approach should be avoided when accessing a remote file system via a mount/share unless that file system supports distributed file locks. - rename - rename is for using a try to rename the file as a test if we can get exclusive read-lock. - idempotent - (only for file component) idempotent is for using a idempotentRepository as the read-lock. This allows to use read locks that supports clustering if the idempotent repository implementation supports that. - idempotent-changed - (only for file component) idempotent-changed is for using a idempotentRepository and changed as the combined read-lock. This allows to use read locks that supports clustering if the idempotent repository implementation supports that. - idempotent-rename - (only for file component) idempotent-rename is for using a idempotentRepository and rename as the combined read-lock. This allows to use read locks that supports clustering if the idempotent repository implementation supports that. Notice: The various read locks is not all suited to work in clustered mode, where concurrent consumers on different nodes is competing for the same files on a shared file system. The markerFile using a close to atomic operation to create the empty marker file, but its not guaranteed to work in a cluster. The fileLock may work better but then the file system need to support distributed file locks, and so on. Using the idempotent read lock can support clustering if the idempotent repository supports clustering, such as Hazelcast Component or Infinispan. Enum values: ● none ● markerFile ● fileLock		

Name	● rename Description ● changed	Default	Type
	● idempotent ● idempotent-changed ● idempotent-rename		
readLockCheckInterval (lock)	Interval in millis for the read-lock, if supported by the read lock. This interval is used for sleeping between attempts to acquire the read lock. For example when using the changed read lock, you can set a higher interval period to cater for slow writes. The default of 1 sec. may be too fast if the producer is very slow writing the file. Notice: For FTP the default readLockCheckInterval is 5000. The readLockTimeout value must be higher than readLockCheckInterval, but a rule of thumb is to have a timeout that is at least 2 or more times higher than the readLockCheckInterval. This is needed to ensure that ample time is allowed for the read lock process to try to grab the lock before the timeout was hit.	1000	long
readLockDeleteOrphanLockFiles (lock)	Whether or not read lock with marker files should upon startup delete any orphan read lock files, which may have been left on the file system, if Camel was not properly shutdown (such as a JVM crash). If turning this option to false then any orphaned lock file will cause Camel to not attempt to pickup that file, this could also be due another node is concurrently reading files from the same shared directory.	true	boolean
readLockLoggingLevel (lock)	Logging level used when a read lock could not be acquired. By default a DEBUG is logged. You can change this level, for example to OFF to not have any logging. This option is only applicable for readLock of types: changed, fileLock, idempotent, idempotent-changed, idempotent-rename, rename. Enum values: ● TRACE ● DEBUG ● INFO ● WARN ● ERROR ● OFF	DEBUG	LoggingLevel

Name	Description	Default	Type
readLockMarkerFile (lock)	Whether to use marker file with the changed, rename, or exclusive read lock types. By default a marker file is used as well to guard against other processes picking up the same files. This behavior can be turned off by setting this option to false. For example if you do not want to write marker files to the file systems by the Camel application.	true	boolean
readLockMinAge (lock)	This option is applied only for readLock=changed. It allows to specify a minimum age the file must be before attempting to acquire the read lock. For example use readLockMinAge=300s to require the file is at last 5 minutes old. This can speedup the changed read lock as it will only attempt to acquire files which are at least that given age.	0	long
readLockMinLength (lock)	This option is applied only for readLock=changed. It allows you to configure a minimum file length. By default Camel expects the file to contain data, and thus the default value is 1. You can set this option to zero, to allow consuming zero-length files.	1	long
readLockRemoveOnCommit (lock)	This option is applied only for readLock=idempotent. It allows to specify whether to remove the file name entry from the idempotent repository when processing the file is succeeded and a commit happens. By default the file is not removed which ensures that any race-condition do not occur so another active node may attempt to grab the file. Instead the idempotent repository may support eviction strategies that you can configure to evict the file name entry after X minutes - this ensures no problems with race conditions. See more details at the readLockIdempotentReleaseDelay option.	false	boolean
readLockRemoveOnRollback (lock)	This option is applied only for readLock=idempotent. It allows to specify whether to remove the file name entry from the idempotent repository when processing the file failed and a rollback happens. If this option is false, then the file name entry is confirmed (as if the file did a commit).	true	boolean

Name	Description	Default	Type
readLockTimeout (lock)	Optional timeout in millis for the read-lock, if supported by the read-lock. If the read-lock could not be granted and the timeout triggered, then Camel will skip the file. At next poll Camel, will try the file again, and this time maybe the read-lock could be granted. Use a value of 0 or lower to indicate forever. Currently fileLock, changed and rename support the timeout. Notice: For FTP the default readLockTimeout value is 20000 instead of 10000. The readLockTimeout value must be higher than readLockCheckInterval, but a rule of thumb is to have a timeout that is at least 2 or more times higher than the readLockCheckInterval. This is needed to ensure that ample time is allowed for the read lock process to try to grab the lock before the timeout was hit.	10000	long
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.		int
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.		int
delay (scheduler)	Milliseconds before the next poll.	500	long
greedy (scheduler)	If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts.	1000	long
repeatCount (scheduler)	Specifies a maximum limit of number of fires. So if you set it to 1, the scheduler will only fire once. If you set it to 5, it will only fire five times. A value of zero or negative means fire forever.	0	long

Name	Description	Default	Type
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that. Enum values: • TRACE • DEBUG • INFO • WARN • ERROR • OFF	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz component. Use value spring or quartz for built in scheduler.	none	Object
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for initialDelay and delay options. Enum values: • NANOSECONDS • MICROSECONDS • MILLISECONDS • SECONDS • MINUTES • HOURS • DAYS	MILLISECONDS	TimeUnit

Name	Description	Default	Type
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See <code>ScheduledExecutorService</code> in JDK for details.	true	boolean
account (security)	Account to use for login.		String
password (security)	Password to use for login.		String
username (security)	Username to use for login.		String
shuffle (sort)	To shuffle the list of files (sort in random order).	false	boolean
sortBy (sort)	Built-in sort by using the File Language. Supports nested sorts, so you can have a sort by file name and as a 2nd group sort by modified date.		String
sorter (sort)	Pluggable sorter as a <code>java.util.Comparator</code> class.		Comparator

40.6. FTPS COMPONENT DEFAULT TRUST STORE

When using the **ftpClient**, properties related to SSL with the FTPS component, the trust store accept all certificates. If you only want trust selective certificates, you have to configure the trust store with the **ftpClient.trustStore.xxx** options or by configuring a custom **ftpClient**.

When using **sslContextParameters**, the trust store is managed by the configuration of the provided `SSLContextParameters` instance.

You can configure additional options on the **ftpClient** and **ftpClientConfig** from the URI directly by using the **ftpClient.** or **ftpClientConfig.** prefix.

For example to set the **setDataTimeout** on the **FTPClient** to 30 seconds you can do:

```
from("ftp://foo@myserver?password=secret&ftpClient.dataTimeout=30000").to("bean:foo");
```

You can mix and match and have use both prefixes, for example to configure date format or timezones.

```
from("ftp://foo@myserver?password=secret&ftpClient.dataTimeout=30000&ftpClientConfig.serverLanguageCode=fr").to("bean:foo");
```

You can have as many of these options as you like.

See the documentation of the Apache Commons FTP `FTPClientConfig` for possible options and more details. And as well for Apache Commons FTP `FTPClient`.

If you do not like having many and long configuration in the url you can refer to the **ftpClient** or **ftpClientConfig** to use by letting Camel lookup in the Registry for it.

For example:

```
<bean id="myConfig" class="org.apache.commons.net.ftp.FTPClientConfig">
  <property name="lenientFutureDates" value="true"/>
  <property name="serverLanguageCode" value="fr"/>
</bean>
```

And then let Camel lookup this bean when you use the # notation in the url.

```
from("ftp://foo@myserver?password=secret&ftpClientConfig=#myConfig").to("bean:foo");
```

40.7. EXAMPLES

```
ftp://someone@someftpserver.com/public/upload/images/holiday2008?password=secret&binary=true
ftp://someoneelse@someotherftpserver.co.uk:12049/reports/2008/password=secret&binary=false
ftp://publicftpserver.com/download
```

40.8. CONCURRENCY

FTP Consumer does not support concurrency

The FTP consumer (with the same endpoint) does not support concurrency (the backing FTP client is not thread safe).

You can use multiple FTP consumers to poll from different endpoints. It is only a single endpoint that does not support concurrent consumers.

The FTP producer does **not** have this issue, it supports concurrency.

40.9. MORE INFORMATION

This component is an extension of the File component. So there are more samples and details on the File component page.

40.10. DEFAULT WHEN CONSUMING FILES

The FTP consumer will by default leave the consumed files untouched on the remote FTP server. You have to configure it explicitly if you want it to delete the files or move them to another location. For example you can use **delete=true** to delete the files, or use **move=.done** to move the files into a hidden done sub directory.

The regular File consumer is different as it will by default move files to a **.camel** sub directory. The reason Camel does **not** do this by default for the FTP consumer is that it may lack permissions by default to be able to move or delete files.

40.10.1. limitations

The option **readLock** can be used to force Camel **not** to consume files that is currently in the progress of being written. However, this option is turned off by default, as it requires that the user has write access. See the options table at File2 for more details about read locks.

There are other solutions to avoid consuming files that are currently being written over FTP; for instance, you can write to a temporary destination and move the file after it has been written.

When moving files using **move** or **preMove** option the files are restricted to the FTP_ROOT folder. That prevents you from moving files outside the FTP area. If you want to move files to another area you can use soft links and move files into a soft linked folder.

40.11. MESSAGE HEADERS

The following message headers can be used to affect the behavior of the component

Header	Description
CamelFileName	Specifies the output file name (relative to the endpoint directory) to be used for the output message when sending to the endpoint. If this is not present and no expression either, then a generated message ID is used as the filename instead.
CamelFileNameProduced	The actual filepath (path + name) for the output file that was written. This header is set by Camel and its purpose is providing end-users the name of the file that was written.
CamelFileNameConsumed	The file name of the file consumed
CamelFileHost	The remote hostname.
CamelFileLocalWorkPath	Path to the local work file, if local work directory is used.

In addition the FTP/FTPS consumer and producer will enrich the Camel **Message** with the following headers

Header	Description
CamelFtpReplyCode	The FTP client reply code (the type is a integer)
CamelFtpReplyString	The FTP client reply string

40.11.1. Exchange Properties

Camel sets the following exchange properties

Header	Description
CamelBatchIndex	Current index out of total number of files being consumed in this batch.
CamelBatchSize	Total number of files being consumed in this batch.

Header	Description
CamelBatchComplete	True if there are no more files in this batch.

40.12. ABOUT TIMEOUTS

The two set of libraries (see top) has different API for setting timeout. You can use the **connectTimeout** option for both of them to set a timeout in millis to establish a network connection. An individual **soTimeout** can also be set on the FTP/FTPS, which corresponds to using **ftpClient.soTimeout**. Notice SFTP will automatically use **connectTimeout** as its **soTimeout**. The **timeout** option only applies for FTP/FTPS as the data timeout, which corresponds to the **ftpClient.dataTimeout** value. All timeout values are in millis.

40.13. USING LOCAL WORK DIRECTORY

Camel supports consuming from remote FTP servers and downloading the files directly into a local work directory. This avoids reading the entire remote file content into memory as it is streamed directly into the local file using **FileOutputStream**.

Camel will store to a local file with the same name as the remote file, though with **.inprogress** as extension while the file is being downloaded. Afterwards, the file is renamed to remove the **.inprogress** suffix. And finally, when the Exchange is complete the local file is deleted.

So if you want to download files from a remote FTP server and store it as files then you need to route to a file endpoint such as:

```
from("ftp://someone@someserver.com?password=secret&localWorkDirectory=/tmp").to("file://inbox");
```

NOTE

The route above is ultra efficient as it avoids reading the entire file content into memory. It will download the remote file directly to a local file stream. The **java.io.File** handle is then used as the Exchange body. The file producer leverages this fact and can work directly on the work file **java.io.File** handle and perform a **java.io.File.rename** to the target filename. As Camel knows it's a local work file, it can optimize and use a rename instead of a file copy, as the work file is meant to be deleted anyway.

40.14. STEPWISE CHANGING DIRECTORIES

Camel FTP can operate in two modes in terms of traversing directories when consuming files (eg downloading) or producing files (eg uploading)

- stepwise
- not stepwise

You may want to pick either one depending on your situation and security issues. Some Camel end users can only download files if they use stepwise, while others can only download if they do not.

You can use the **stepwise** option to control the behavior.

Note that stepwise changing of directory will in most cases only work when the user is confined to it's home directory and when the home directory is reported as "/".

The difference between the two of them is best illustrated with an example. Suppose we have the following directory structure on the remote FTP server we need to traverse and download files:

```
/
/one
/one/two
/one/two/sub-a
/one/two/sub-b
```

And that we have a file in each of sub-a (a.txt) and sub-b (b.txt) folder.

40.15. USING STEPWISE=TRUE (DEFAULT MODE)

```
TYPE A
200 Type set to A
PWD
257 "/" is current directory.
CWD one
250 CWD successful. "/one" is current directory.
CWD two
250 CWD successful. "/one/two" is current directory.
SYST
215 UNIX emulated by FileZilla
PORT 127,0,0,1,17,94
200 Port command successful
LIST
150 Opening data channel for directory list.
226 Transfer OK
CWD sub-a
250 CWD successful. "/one/two/sub-a" is current directory.
PORT 127,0,0,1,17,95
200 Port command successful
LIST
150 Opening data channel for directory list.
226 Transfer OK
CDUP
200 CDUP successful. "/one/two" is current directory.
CWD sub-b
250 CWD successful. "/one/two/sub-b" is current directory.
PORT 127,0,0,1,17,96
200 Port command successful
LIST
150 Opening data channel for directory list.
226 Transfer OK
CDUP
200 CDUP successful. "/one/two" is current directory.
CWD /
250 CWD successful. "/" is current directory.
PWD
257 "/" is current directory.
CWD one
250 CWD successful. "/one" is current directory.
```

```
CWD two
250 CWD successful. "/one/two" is current directory.
PORT 127,0,0,1,17,97
200 Port command successful
RETR foo.txt
150 Opening data channel for file transfer.
226 Transfer OK
CWD /
250 CWD successful. "/" is current directory.
PWD
257 "/" is current directory.
CWD one
250 CWD successful. "/one" is current directory.
CWD two
250 CWD successful. "/one/two" is current directory.
CWD sub-a
250 CWD successful. "/one/two/sub-a" is current directory.
PORT 127,0,0,1,17,98
200 Port command successful
RETR a.txt
150 Opening data channel for file transfer.
226 Transfer OK
CWD /
250 CWD successful. "/" is current directory.
PWD
257 "/" is current directory.
CWD one
250 CWD successful. "/one" is current directory.
CWD two
250 CWD successful. "/one/two" is current directory.
CWD sub-b
250 CWD successful. "/one/two/sub-b" is current directory.
PORT 127,0,0,1,17,99
200 Port command successful
RETR b.txt
150 Opening data channel for file transfer.
226 Transfer OK
CWD /
250 CWD successful. "/" is current directory.
QUIT
221 Goodbye
disconnected.
```

As you can see when stepwise is enabled, it will traverse the directory structure using CD xxx.

40.16. USING STEPWISE=FALSE

```
230 Logged on
TYPE A
200 Type set to A
SYST
215 UNIX emulated by FileZilla
PORT 127,0,0,1,4,122
200 Port command successful
LIST one/two
```

```

150 Opening data channel for directory list
226 Transfer OK
PORT 127,0,0,1,4,123
200 Port command successful
LIST one/two/sub-a
150 Opening data channel for directory list
226 Transfer OK
PORT 127,0,0,1,4,124
200 Port command successful
LIST one/two/sub-b
150 Opening data channel for directory list
226 Transfer OK
PORT 127,0,0,1,4,125
200 Port command successful
RETR one/two/foo.txt
150 Opening data channel for file transfer.
226 Transfer OK
PORT 127,0,0,1,4,126
200 Port command successful
RETR one/two/sub-a/a.txt
150 Opening data channel for file transfer.
226 Transfer OK
PORT 127,0,0,1,4,127
200 Port command successful
RETR one/two/sub-b/b.txt
150 Opening data channel for file transfer.
226 Transfer OK
QUIT
221 Goodbye
disconnected.

```

As you can see when not using stepwise, there are no CD operation invoked at all.

40.17. SAMPLES

In the sample below we set up Camel to download all the reports from the FTP server once every hour (60 min) as BINARY content and store it as files on the local file system.

And the route using XML DSL:

```

<route>
  <from uri="ftp://scott@localhost/public/reports?
password=tiger&binary=true&delay=60000"/>
  <to uri="file://target/test-reports"/>
</route>

```

40.17.1. Consuming a remote FTPS server (implicit SSL) and client authentication

```

from("ftps://admin@localhost:2222/public/camel?
password=admin&securityProtocol=SSL&implicit=true
  &ftpClient.keyStore.file=./src/test/resources/server.jks
  &ftpClient.keyStore.password=password&ftpClient.keyStore.keyPassword=password")
.to("bean:foo");

```

40.17.2. Consuming a remote FTPS server (explicit TLS) and a custom trust store configuration

```
from("ftps://admin@localhost:2222/public/camel?
password=admin&ftpClient.trustStore.file=./src/test/resources/server.jks&ftpClient.trustStore.password=
password")
.to("bean:foo");
```

40.18. CUSTOM FILTERING

Camel supports pluggable filtering strategies. This strategy it to use the build in **org.apache.camel.component.file.GenericFileFilter** in Java. You can then configure the endpoint with such a filter to skip certain filters before being processed.

In the sample we have built our own filter that only accepts files starting with report in the filename.

And then we can configure our route using the **filter** attribute to reference our filter (using # notation) that we have defined in the spring XML file:

```
<!-- define our sorter as a plain spring bean -->
<bean id="myFilter" class="com.mycompany.MyFileFilter"/>

<route>
  <from uri="ftp://someuser@someftpserver.com?password=secret&filter=#myFilter"/>
  <to uri="bean:processInbox"/>
</route>
```

40.19. FILTERING USING ANT PATH MATCHER

The ANT path matcher is a filter that is shipped out-of-the-box in the **camel-spring** jar. So you need to depend on **camel-spring** if you are using Maven.

The reason is that we leverage Spring's [AntPathMatcher](#) to do the actual matching.

The file paths are matched with the following rules:

- **?** matches one character
- ***** matches zero or more characters
- ****** matches zero or more directories in a path

The sample below demonstrates how to use it:

40.20. USING A PROXY WITH SFTP

To use an HTTP proxy to connect to your remote host, you can configure your route in the following way:

```
<!-- define our sorter as a plain spring bean -->
<bean id="proxy" class="com.jcraft.jsch.ProxyHTTP">
  <constructor-arg value="localhost"/>
  <constructor-arg value="7777"/>
</bean>
```

```
<route>
  <from uri="sftp://localhost:9999/root?username=admin&password=admin&proxy=#proxy"/>
  <to uri="bean:processFile"/>
</route>
```

You can also assign a user name and password to the proxy, if necessary. Please consult the documentation for **com.jcraft.jsch.Proxy** to discover all options.

40.21. SETTING PREFERRED SFTP AUTHENTICATION METHOD

If you want to explicitly specify the list of authentication methods that should be used by **sftp** component, use **preferredAuthentications** option. If for example you would like Camel to attempt to authenticate with private/public SSH key and fallback to user/password authentication in the case when no public key is available, use the following route configuration:

```
from("sftp://localhost:9999/root?
username=admin&password=admin&preferredAuthentications=publickey,password").
to("bean:processFile");
```

40.22. CONSUMING A SINGLE FILE USING A FIXED NAME

When you want to download a single file and knows the file name, you can use **fileName=myFileName.txt** to tell Camel the name of the file to download. By default the consumer will still do a FTP LIST command to do a directory listing and then filter these files based on the **fileName** option. Though in this use-case it may be desirable to turn off the directory listing by setting **useList=false**. For example the user account used to login to the FTP server may not have permission to do a FTP LIST command. So you can turn off this with **useList=false**, and then provide the fixed name of the file to download with **fileName=myFileName.txt**, then the FTP consumer can still download the file. If the file for some reason does not exist, then Camel will by default throw an exception, you can turn this off and ignore this by setting **ignoreFileNotFoundOrPermissionError=true**.

For example to have a Camel route that pickup a single file, and delete it after use you can do

```
from("ftp://admin@localhost:21/nolist/?
password=admin&stepwise=false&useList=false&ignoreFileNotFoundOrPermissionError=true&fileName
=report.txt&delete=true")
.to("activemq:queue:report");
```

Notice that we have used all the options we talked above.

You can also use this with **ConsumerTemplate**. For example to download a single file (if it exists) and grab the file content as a String type:

```
String data = template.retrieveBodyNoWait("ftp://admin@localhost:21/nolist/?
password=admin&stepwise=false&useList=false&ignoreFileNotFoundOrPermissionError=true&fileName
=report.txt&delete=true", String.class);
```

40.23. DEBUG LOGGING

This component has log level **TRACE** that can be helpful if you have problems.

40.24. SPRING BOOT AUTO-CONFIGURATION

The component supports 13 options, which are listed below.

Name	Description	Default	Type
camel.component.ftp.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.ftp.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.ftp.enabled	Whether to enable auto configuration of the ftp component. This is enabled by default.		Boolean
camel.component.ftp.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.ftp.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.ftp.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.ftp.enabled	Whether to enable auto configuration of the ftps component. This is enabled by default.		Boolean
camel.component.ftp.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.ftp.use-global-ssl-context-parameters	Enable usage of global SSL context parameters.	false	Boolean
camel.component.sftp.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.sftp.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean

Name	Description	Default	Type
camel.component.sftp.enabled	Whether to enable auto configuration of the sftp component. This is enabled by default.		Boolean
camel.component.sftp.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 41. GOOGLE BIGQUERY

Since Camel 2.20

Only producer is supported.

The Google Bigquery component provides access to the [Cloud BigQuery Infrastructure](https://developers.google.com/api-client-library/java/apis/bigquery/v2) via the link: <https://developers.google.com/api-client-library/java/apis/bigquery/v2> [Google Client Services API].

The current implementation does not use gRPC.

The current implementation does not support querying BigQuery, it is only a producer.

41.1. DEPENDENCIES

When using **google-bigquery** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-google-bigquery-starter</artifactId>
</dependency>
```

41.2. AUTHENTICATION CONFIGURATION

Google BigQuery component authentication is targeted for use with the GCP Service Accounts. For more information please refer to [Google Cloud Platform Auth Guide](#).

Google security credentials can be set explicitly by providing the path to the GCP credentials file location.

Or they are set implicitly, where the connection factory falls back on [Application Default Credentials](#).

When you have the **service account key** you can provide authentication credentials to your application code. Google security credentials can be set through the component endpoint:

```
String endpoint = "google-bigquery://project-id:datasetId[:tableId]?
serviceAccountKey=/home/user/Downloads/my-key.json";
```

You can also use the base64 encoded content of the authentication credentials file if you don't want to set a file system path.

```
String endpoint = "google-bigquery://project-id:datasetId[:tableId]?serviceAccountKey=base64:
<base64 encoded>";
```

Or by setting the environment variable **GOOGLE_APPLICATION_CREDENTIALS**:

```
export GOOGLE_APPLICATION_CREDENTIALS="/home/user/Downloads/my-key.json"
```

41.3. URI FORMAT

```
google-bigquery://project-id:datasetId[:tableId]?[options]
```

41.4. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

41.4.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).
- directly in the Java code.

41.4.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

41.5. COMPONENT OPTIONS

The Google BigQuery component supports 5 options, which are listed below.

Name	Description	Default	Type
connectionFactory (producer)	Autowired ConnectionFactory to obtain connection to Bigquery Service. If not provided the default one will be used.		GoogleBigQueryConnectionFactory
datasetId (producer)	BigQuery Dataset Id.		String
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
projectId (producer)	Google Cloud Project Id.		String
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

41.6. ENDPOINT OPTIONS

The Google BigQuery endpoint is configured using URI syntax:

```
google-bigquery:projectId:datasetId:tableId
```

with the following path and query parameters:

41.6.1. Path Parameters (3 parameters)

Name	Description	Default	Type
projectId (common)	Required Google Cloud Project Id.		String

Name	Description	Default	Type
datasetId (common)	Required BigQuery Dataset Id.		String
tableId (common)	BigQuery table id.		String

41.6.2. Query Parameters (4 parameters)

Name	Description	Default	Type
connectionFactory (producer)	Autowired ConnectionFactory to obtain connection to Bigquery Service. If not provided the default one will be used.		GoogleBigQueryConnectionFactory
useAsInsertId (producer)	Field name to use as insert id.		String
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
serviceAccountKey (security)	Service account key in json format to authenticate an application as a service account to google cloud platform.		String

41.7. MESSAGE HEADERS

The Google BigQuery component supports 4 message header(s), which is/are listed below:

Name	Description	Default	Type
CamelGoogleBigQueryTableSuffix (producer) Constant: TABLE_SUFFIX	Table suffix to use when inserting data.		String

Name	Description	Default	Type
CamelGoogleBigQueryTableId (producer) Constant: TABLE_ID	Table id where data will be submitted. If specified will override endpoint configuration.		String
CamelGoogleBigQueryInsertId (producer) Constant: INSERT_ID	InsertId to use when inserting data.		String
CamelGoogleBigQueryPartitionDecorator (producer) Constant: PARTITION_DECORATOR	Partition decorator to indicate partition to use when inserting data.		String

41.8. PRODUCER ENDPOINTS

Producer endpoints can accept and deliver to BigQuery individual and grouped exchanges alike. Grouped exchanges have **Exchange.GROUPED_EXCHANGE** property set.

Google BigQuery producer will send a grouped exchange in a single api call unless different table suffix or partition decorators are specified in which case it will break it down to ensure data is written with the correct suffix or partition decorator.

Google BigQuery endpoint expects the payload to be either a map or list of maps. A payload containing a map will insert a single row and a payload containing a list of map's will insert a row for each entry in the list.

41.9. TEMPLATE TABLES

Templated tables can be specified using the **GoogleBigQueryConstants.TABLE_SUFFIX** header. For example, the following route will create tables and insert records sharded on a per day basis:

```
from("direct:start")
  .header(GoogleBigQueryConstants.TABLE_SUFFIX, "_${date:now:yyyyMMdd}")
  .to("google-bigquery:sampleDataset:sampleTable")
```

NOTE

It is recommended to use partitioning for this use case.

For more information about Template table, see [Template Tables](#).

41.10. PARTITIONING

Partitioning is specified when creating a table and if set data will be automatically partitioned into separate tables. When inserting data a specific partition can be specified by setting the **GoogleBigQueryConstants.PARTITION_DECORATOR** header on the exchange.

For more information about partitioning, see [Creating partitioned tables](#).

41.11. ENSURING DATA CONSISTENCY

An insert id can be set on the exchange with the header **GoogleBigQueryConstants.INSERT_ID** or by specifying query parameter **useAsInsertId**. As an insert id need to be specified per row, the inserted the exchange header can't be used when the payload is a list. If the payload is a list then the **GoogleBigQueryConstants.INSERT_ID** will be ignored. In that case use the query parameter **useAsInsertId**.

For more information, see [Data consistency](#)

41.12. SPRING BOOT AUTO-CONFIGURATION

The component supports 11 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.google-bigquery-sql.autowired-enabled</code>	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
<code>camel.component.google-bigquery-sql.connection-factory</code>	ConnectionFactory to obtain connection to Bigquery Service. If not provided the default one will be used. The option is a <code>org.apache.camel.component.google.bigquery.GoogleBigQueryConnectionFactory</code> type.		GoogleBigQueryConnectionFactory
<code>camel.component.google-bigquery-sql.enabled</code>	Whether to enable auto configuration of the google-bigquery-sql component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.google-bigquery-sql.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.google-bigquery-sql.project-id	Google Cloud Project Id.		String
camel.component.google-bigquery.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.google-bigquery.connection-factory	ConnectionFactory to obtain connection to Bigquery Service. If not provided the default one will be used. The option is a org.apache.camel.component.google.bigquery.GoogleBigQueryConnectionFactory type.		GoogleBigQueryConnectionFactory
camel.component.google-bigquery.dataset-id	BigQuery Dataset Id.		String
camel.component.google-bigquery.enabled	Whether to enable auto configuration of the google-bigquery component. This is enabled by default.		Boolean

Name	Description	Default	Type
<code>camel.component.google-bigquery.lazy-start-producer</code>	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
<code>camel.component.google-bigquery.project-id</code>	Google Cloud Project Id.		String

CHAPTER 42. GOOGLE PUBSUB

Since Camel 2.19

Both producer and consumer are supported.

The Google Pubsub component provides access to the [Cloud Pub/Sub Infrastructure](#) via the [Google Cloud Java Client for Google Cloud Pub/Sub](#).

42.1. DEPENDENCIES

When using **google-pubsub** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-google-pubsub-starter</artifactId>
</dependency>
```

42.2. URI FORMAT

The Google Pubsub Component uses the following URI format:

```
google-pubsub://project-id:destinationName?[options]
```

Destination Name can be either a topic or a subscription name.

42.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

42.3.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).
- directly in the Java code.

42.3.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

42.4. COMPONENT OPTIONS

The Google Pubsub component supports 10 options, which are listed below.

Name	Description	Default	Type
authenticate (common)	Use Credentials when interacting with PubSub service (no authentication is required when using emulator).	true	boolean
endpoint (common)	Endpoint to use with local Pub/Sub emulator.		String
serviceAccountKey (common)	The Service account key that can be used as credentials for the PubSub publisher/subscriber. It can be loaded by default from classpath, but you can prefix with classpath:, file:, or http: to load the resource from different systems.		String
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean

Name	Description	Default	Type
synchronousPullRetryableCodes (consumer)	Comma-separated list of additional retryable error codes for synchronous pull. By default the PubSub client library retries ABORTED, UNAVAILABLE, UNKNOWN.		String
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
publisherCacheSize (producer)	Maximum number of producers to cache. This could be increased if you have producers for lots of different topics.		int
publisherCacheTimeout (producer)	How many milliseconds should each producer stay alive in the cache.		int
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
publisherTerminationTimeout (advanced)	How many milliseconds should a producer be allowed to terminate.		int

42.5. ENDPOINT OPTIONS

The Google Pubsub endpoint is configured using URI syntax:

```
google-pubsub:projectId:destinationName
```

with the following path and query parameters:

42.5.1. Path Parameters (2 parameters)

Name	Description	Default	Type
projectId (common)	Required The Google Cloud PubSub Project Id.		String
destinationName (common)	Required The Destination Name. For the consumer this will be the subscription name, while for the producer this will be the topic name.		String

42.5.2. Query Parameters (15 parameters)

Name	Description	Default	Type
authenticate (common)	Use Credentials when interacting with PubSub service (no authentication is required when using emulator).	true	boolean
loggerId (common)	Logger ID to use when a match to the parent route required.		String
serviceAccountKey (common)	The Service account key that can be used as credentials for the PubSub publisher/subscriber. It can be loaded by default from classpath, but you can prefix with classpath:, file:, or http: to load the resource from different systems.		String
ackMode (consumer)	AUTO = exchange gets ack'ed/nack'ed on completion. NONE = downstream process has to ack/nack explicitly. Enum values: ● AUTO ● NONE	AUTO	AckMode
concurrentConsumers (consumer)	The number of parallel streams consuming from the subscription.	1	Integer
maxAckExtensionPeriod (consumer)	Set the maximum period a message ack deadline will be extended. Value in seconds.	3600	int
maxMessagesPerPoll (consumer)	The max number of messages to receive from the server in a single API call.	1	Integer
synchronousPull (consumer)	Synchronously pull batches of messages.	false	boolean

Name	Description	Default	Type
bridgeErrorHandler (consumer (advanced))	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer (advanced))	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		<code>ExceptionHandler</code>
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • <code>InOnly</code> • <code>InOut</code> • <code>InOptionalOut</code>		<code>ExchangePattern</code>
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow <code>CamelContext</code> and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
messageOrderingEnabled (producer (advanced))	Should message ordering be enabled.	false	boolean
pubsubEndpoint (producer (advanced))	Pub/Sub endpoint to use. Required when using message ordering, and ensures that messages are received in order even when multiple publishers are used.		String

Name	Description	Default	Type
serializer (producer (advanced))	Autowired A custom GooglePubsubSerializer to use for serializing message payloads in the producer.		GooglePubsubSerializer

42.6. MESSAGE HEADERS

The Google Pubsub component supports 5 message header(s), which are listed below:

Name	Description	Default	Type
CamelGooglePubsubMessageId (common) Constant: MESSAGE_ID	The ID of the message, assigned by the server when the message is published.		String
CamelGooglePubsubMsgAckId (consumer) Constant: ACK_ID	The ID used to acknowledge the received message.		String
CamelGooglePubsubPublishTime (consumer) Constant: PUBLISH_TIME	The time at which the message was published.		Timestamp
CamelGooglePubsubAttributes (common) Constant: ATTRIBUTES	The attributes of the message.		Map
CamelGooglePubsubOrderingKey (producer) Constant: ORDERING_KEY	If non-empty, identifies related messages for which publish order should be respected.		String

42.7. PRODUCER ENDPOINTS

Producer endpoints can accept and deliver to PubSub individual and grouped exchanges alike. Grouped exchanges have **Exchange.GROUPED_EXCHANGE** property set.

Google PubSub expects the payload to be byte[] array, Producer endpoints will send:

- String body as byte[] encoded as UTF-8
- byte[] body as is
- Everything else will be serialised into byte[] array

A Map set as message header **GooglePubsubConstants.ATTRIBUTES** will be sent as PubSub attributes.

Google PubSub supports ordered message delivery.

To enable this set the options `messageOrderingEnabled` to true, and the `pubsubEndpoint` to a GCP region.

When producing messages set the message header **GooglePubsubConstants.ORDERING_KEY**. This will be set as the PubSub `orderingKey` for the message.

More information in [Ordering messages](#).

Once exchange has been delivered to PubSub the PubSub Message ID will be assigned to the header **GooglePubsubConstants.MESSAGE_ID**.

42.8. CONSUMER ENDPOINTS

Google PubSub will redeliver the message if it has not been acknowledged within the time period set as a configuration option on the subscription.

The component will acknowledge the message once exchange processing has been completed.

If the route throws an exception, the exchange is marked as failed and the component will NACK the message - it will be redelivered immediately.

To ack/nack the message the component uses Acknowledgement ID stored as header **GooglePubsubConstants.ACK_ID**. If the header is removed or tampered with, the ack will fail and the message will be redelivered again after the ack deadline.

42.9. MESSAGE BODY

The consumer endpoint returns the content of the message as byte[] - exactly as the underlying system sends it. It is up for the route to convert/unmarshall the contents.

42.10. AUTHENTICATION CONFIGURATION

By default this component acquires credentials using **GoogleCredentials.getDefault()**. This behavior can be disabled by setting *authenticate* option to **false**, in which case requests to Google API will be made without authentication details. This is only desirable when developing against an emulator. This behavior can be altered by supplying a path to a service account key file.

42.11. ROLLBACK AND REDELIVERY

The rollback for Google PubSub relies on the idea of the Acknowledgement Deadline - the time period where Google PubSub expects to receive the acknowledgement. If the acknowledgement has not been received, the message is redelivered.

Google provides an API to extend the deadline for a message.

More information in [Google PubSub Documentation](#).

So, rollback is effectively a deadline extension API call with zero value - i.e. deadline is reached now and message can be redelivered to the next consumer.

It is possible to delay the message redelivery by setting the acknowledgement deadline explicitly for the rollback by setting the message header **GooglePubsubConstants.ACK_DEADLINE** to the value in seconds.

42.12. SPRING BOOT AUTO-CONFIGURATION

The component supports 11 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.google-pubsub.authenticate</code>	Use Credentials when interacting with PubSub service (no authentication is required when using emulator).	true	Boolean
<code>camel.component.google-pubsub.autowired-enabled</code>	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
<code>camel.component.google-pubsub.bridge-error-handler</code>	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
<code>camel.component.google-pubsub.enabled</code>	Whether to enable auto configuration of the google-pubsub component. This is enabled by default.		Boolean
<code>camel.component.google-pubsub.endpoint</code>	Endpoint to use with local Pub/Sub emulator.		String

Name	Description	Default	Type
camel.component.google-pubsub.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.google-pubsub.publisher-cache-size	Maximum number of producers to cache. This could be increased if you have producers for lots of different topics.		Integer
camel.component.google-pubsub.publisher-cache-timeout	How many milliseconds should each producer stay alive in the cache.		Integer
camel.component.google-pubsub.publisher-termination-timeout	How many milliseconds should a producer be allowed to terminate.		Integer
camel.component.google-pubsub.service-account-key	The Service account key that can be used as credentials for the PubSub publisher/subscriber. It can be loaded by default from classpath, but you can prefix with classpath:, file:, or http: to load the resource from different systems.		String
camel.component.google-pubsub.synchronous-pull-retryable-codes	Comma-separated list of additional retryable error codes for synchronous pull. By default the PubSub client library retries ABORTED, UNAVAILABLE, UNKNOWN.		String

CHAPTER 43. GOOGLE SECRET MANAGER

Only producer is supported

The Google Secret Manager component provides access to [Google Cloud Secret Manager](#).

43.1. DEPENDENCIES

When using **camel-aws-secrets-manager** with Red Hat build of Camel Spring Boot, add the following Maven dependency to your **pom.xml** to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-google-secret-manager-starter</artifactId>
</dependency>
```

43.2. AUTHENTICATION CONFIGURATION

Google Secret Manager component authentication is targeted for the use with the GCP Service Accounts. For more information, please refer to [Google Cloud Authentication](#).

When you have the **service account key**, you can provide authentication credentials to your application code. Google security credentials can be set through the component endpoint:

```
String endpoint = "google-secret-manager://myCamelFunction?
serviceAccountKey=/home/user/Downloads/my-key.json";
```

Or by setting the environment variable **GOOGLE_APPLICATION_CREDENTIALS**:

```
export GOOGLE_APPLICATION_CREDENTIALS="/home/user/Downloads/my-key.json"
```

43.3. URI FORMAT

```
google-secret-manager://functionName[?options]
```

You can append query options to the URI in the following format,

```
`?options=value&option2=value&...`
```

For example, in order to call the function **myCamelFunction** from the project **myProject** and location **us-central1**, use the following snippet:

```
from("google-secret-manager://myProject?serviceAccountKey=/home/user/Downloads/my-
key.json&operation=createSecret")
.to("direct:test");
```

43.4. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

43.4.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).
- directly in the Java code.

43.4.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

43.5. COMPONENT OPTIONS

The Google Secret Manager component supports 2 options, which are listed below.

Name	Description	Default	Type
------	-------------	---------	------

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

43.6. ENDPOINT OPTIONS

The Google Secret Manager endpoint is configured using URI syntax:

```
google-secret-manager:project
```

With the following *path* and *query* parameters:

43.6.1. Path Parameters (1 parameters)

Name	Description	Default	Type
project (common)	Required The Google Cloud Project Id name related to the Secret Manager.		String

43.6.2. Query Parameters (5 parameters)

Name	Description	Default	Type
serviceAccountKey (common)	Service account key to authenticate an application as a service account.		String

Name	Description	Default	Type
operation (producer)	The operation to perform on the producer. Enum values: • createSecret		GoogleSecretManagerOperations
pojoRequest (producer)	Specifies if the request is a pojo request.	false	boolean
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
client (advanced)	Autowired The client to use during service invocation.		SecretManagerServiceClient

43.7. MESSAGE HEADERS

The Google Secret Manager component supports 3 message header(s), which is/are listed below:

Name	Description	Default	Type
GoogleSecretManagerOperation (producer) Constant: OPERATION	The operation to perform. Enum values: • createSecret • getSecretVersion • deleteSecret • listSecrets		GoogleSecretManagerOperations

Name	Description	Default	Type
CamelGoogleSecretManagerSecretId (producer) Constant: SECRET_ID	The id of the secret.		String
CamelGoogleSecretManagerVersionId (producer) Constant: VERSION_ID	The version of the secret.	latest	String

43.7.1. Using GCP Secret Manager Properties Source

To use GCP Secret Manager, you need to provide **serviceAccountKey** file and GCP **projectId**. This can be done using environmental variables before starting the application:

```
export $CAMEL_VAULT_GCP_SERVICE_ACCOUNT_KEY=file://path/to/service.accountkey
export $CAMEL_VAULT_GCP_PROJECT_ID=projectId
```

You can also configure the credentials in the **application.properties** file as follows:

```
camel.vault.gcp.serviceAccountKey = serviceAccountKey
camel.vault.gcp.projectId = projectId
```

If you want to use the [GCP default client instance](#) , you will need to provide the following env variables:

```
export $CAMEL_VAULT_GCP_USE_DEFAULT_INSTANCE=true
export $CAMEL_VAULT_GCP_PROJECT_ID=projectId
```

You can also configure the credentials in the **application.properties** file as follows:

```
camel.vault.gcp.useDefaultInstance = true
camel.vault.gcp.projectId = region
```

NOTE

camel.vault.gcp configuration only applies to the Google Secret Manager properties function (for example, when resolving properties). When using the **operation** option to create, get, list secrets etc., you should provide the usual options for connecting to GCP Services.

At this point you can reference a property in the following way by using **gcp:** as prefix in the **{{ }}** syntax:

```
<camelContext>
  <route>
    <from uri="direct:start"/>
    <to uri="{{gcp:route}}"/>
  </route>
</camelContext>
```

Where **route** will be the name of the secret stored in the GCP Secret Manager Service.

You could specify a default value in case the secret is not present on GCP Secret Manager:

```
<camelContext>
  <route>
    <from uri="direct:start"/>
    <to uri="{{gcp:route:default}}"/>
  </route>
</camelContext>
```

In this case, if the secret doesn't exist, the property will fall back to **default** as value.

Also, you can get a particular field of the secret, if you have, for example, a secret named database of this form:

```
{
  "username": "admin",
  "password": "password123",
  "engine": "postgres",
  "host": "127.0.0.1",
  "port": "3128",
  "dbname": "db"
}
```

You can get a single secret value in your route, for example:

```
<camelContext>
  <route>
    <from uri="direct:start"/>
    <log message="Username is {{gcp:database/username}}"/>
  </route>
</camelContext>
```

Or re-use the property as part of an endpoint.

You could specify a default value in case the particular field of secret is not present on GCP Secret Manager:

```
<camelContext>
  <route>
    <from uri="direct:start"/>
    <log message="Username is {{gcp:database/username:admin}}"/>
  </route>
</camelContext>
```

In this case, if the secret doesn't exist or the secret exists, but the username field is not part of the secret, the property will fall back to "admin" as value.

There is also the syntax to get a particular version of the secret for both the approach, with field/default value specified or only with secret:

```
<camelContext>
  <route>
    <from uri="direct:start"/>
    <to uri="{{gcp:route@1}}"/>
  </route>
</camelContext>
```

This approach will return the RAW route secret with version '1'.

```
<camelContext>
  <route>
    <from uri="direct:start"/>
    <to uri="{{gcp:route:default@1}}"/>
  </route>
</camelContext>
```

This approach will return the route secret value with version '1' or default value in case the secret doesn't exist or the version doesn't exist.

```
<camelContext>
  <route>
    <from uri="direct:start"/>
    <log message="Username is {{gcp:database/username:admin@1}}"/>
  </route>
</camelContext>
```

This approach will return the username field of the database secret with version '1' or admin in case the secret doesn't exist or the version doesn't exist.

There are only two requirements:

- Adding **camel-google-secret-manager** JAR to your Camel application.
- Give the service account used permissions to do operation at secret management level, (for example, accessing the secret payload, or being admin of secret manager service)

43.7.2. Automatic CamelContext reloading on Secret Refresh

Being able to reload Camel context on a Secret Refresh is achieved by specifying the usual credentials (the same used for Google Secret Manager Property Function).

With Environment variables:

```
export $CAMEL_VAULT_GCP_USE_DEFAULT_INSTANCE=true
export $CAMEL_VAULT_GCP_PROJECT_ID=projectId
```

or as plain Camel main properties:

```
camel.vault.gcp.useDefaultInstance = true
camel.vault.gcp.projectId = projectId
```

Or by specifying a path to a service account key file, instead of using the default instance.

To enable the automatic refresh, you will need to set the additional properties:

```
camel.vault.gcp.projectId= projectId
camel.vault.gcp.refreshEnabled=true
camel.vault.gcp.refreshPeriod=60000
camel.vault.gcp.secrets=hello*
camel.vault.gcp.subscriptionName=subscriptionName
camel.main.context-reload-enabled = true
```

where **camel.vault.gcp.refreshEnabled** will enable the automatic context reload, **camel.vault.gcp.refreshPeriod** is the interval of time between two different checks for update events and **camel.vault.gcp.secrets** is a regex representing the secrets we want to track for updates.

Note that **camel.vault.gcp.secrets** is not mandatory. If not specified the task responsible for checking updates events will take into accounts or the properties with an **gcp:** prefix.

The **camel.vault.gcp.subscriptionName** is the subscription name created in relation to the Google PubSub topic associated with the tracked secrets.

This mechanism while making use of the notification system related to Google Secret Manager: through this feature, every secret could be associated with one up to ten Google Pubsub Topics. These topics will receive events related to the life cycle of the secret.

There are only two requirements:

- Adding **camel-google-secret-manager** JAR to your Camel application.
- Give the service account used permissions to do operation at secret management level, (for example, accessing the secret payload, or being admin of secret manager service and also have permission over the Pubsub service).

43.7.3. Automatic CamelContext reloading on Secret Refresh - Required infrastructure's creation

you need to install the gcloud cli from the <https://cloud.google.com/sdk/docs/install>. Once the Cli has been installed we can proceed to log in and to set up the project with the following commands:

```
gcloud auth login
```

and

```
gcloud projects create <projectId> --name="GCP Secret Manager Refresh"
```

The project will need a service identity for using secret manager service which you can obtain through the command:

```
gcloud beta services identity create --service "secretmanager.googleapis.com" --project <project_id>
```

The following command will provide a service account name that we need to export:

```
export SM_SERVICE_ACCOUNT="service-...."
```

Since we want to have notifications about events related to a specific secret through a Google Pubsub topic we'll need to create a topic for this purpose with the following command:

```
gcloud pubsub topics create "projects/<project_id>/topics/pubsub-gcp-sec-refresh"
```

The service account will need Secret Manager authorization to publish messages on the topic just created, so we'll need to add an iam policy binding with the following command:

```
gcloud pubsub topics add-iam-policy-binding pubsub-gcp-sec-refresh --member  
"serviceAccount:${SM_SERVICE_ACCOUNT}" --role "roles/pubsub.publisher" --project <project_id>
```

We now need to create a subscription to the **pubsub-gcp-sec-refresh** just created and call it **sub-gcp-sec-refresh** with the following command:

```
gcloud pubsub subscriptions create "projects/<project_id>/subscriptions/sub-gcp-sec-refresh" --topic  
"projects/<project_id>/topics/pubsub-gcp-sec-refresh"
```

Now we need to create a service account for running our application:

```
gcloud iam service-accounts create gcp-sec-refresh-sa --description="GCP Sec Refresh SA" --  
project <project_id>
```

Let's give the SA an owner role:

```
gcloud projects add-iam-policy-binding <project_id> --member="serviceAccount:gcp-sec-refresh-  
sa@<project_id>.iam.gserviceaccount.com" --role="roles/owner"
```

Now we should create a Service account key file for the just create SA:

```
gcloud iam service-accounts keys create <project_id>.json --iam-account=gcp-sec-refresh-  
sa@<project_id>.iam.gserviceaccount.com
```

Let's enable the Secret Manager API for our project.

```
gcloud services enable secretmanager.googleapis.com --project <project_id>
```

Also enable the PubSub API as follows:

```
gcloud services enable pubsub.googleapis.com --project <project_id>
```

If needed enable also the Billing API.

Now it's time to create our secret, with topic notification:

```
gcloud secrets create <secret_name> --topics=projects/<project_id>/topics/pubsub-gcp-sec-refresh --  
project=<project_id>
```

And add the value

```
gcloud secrets versions add <secret_name> --data-file=<json_secret> --project=<project_id>
```

You could now use the `projectId` and the service account json file to recover the secret.

43.7.4. Google Secret Manager Producer operations

Google Functions component provides the following operation on the producer side:

- **createSecret**
- **getSecretVersion**
- **deleteSecret**
- **listSecrets**

If you don't specify an operation by default, the producer will use the **createSecret** operation.

43.7.5. Google Secret Manager Producer Operation examples

- **createSecret**: This operation will create a secret in the Secret Manager service

```
from("direct:start")
  .setHeader("GoogleSecretManagerConstants.SECRET_ID", constant("test"))
  .setBody(constant("hello"))
  .to("google-functions://myProject?serviceAccountKey=/home/user/Downloads/my-
key.json&operation=createSecret")
  .log("body:${body}")
```

- **getSecretVersion**: This operation will retrieve a secret value with the latest version in the Secret Manager service

```
from("direct:start")
  .setHeader("GoogleSecretManagerConstants.SECRET_ID", constant("test"))
  .to("google-functions://myProject?serviceAccountKey=/home/user/Downloads/my-
key.json&operation=getSecretVersion")
  .log("body:${body}")
```

This will log the value of the secret "test".

- **deleteSecret**: This operation will delete a secret

```
from("direct:start")
  .setHeader("GoogleSecretManagerConstants.SECRET_ID", constant("test"))
  .to("google-functions://myProject?serviceAccountKey=/home/user/Downloads/my-
key.json&operation=deleteSecret")
```

- **listSecrets**: This operation will return the secrets' list for the project `myProject`

```
from("direct:start")
  .setHeader("GoogleSecretManagerConstants.SECRET_ID", constant("test"))
  .to("google-functions://myProject?serviceAccountKey=/home/user/Downloads/my-
key.json&operation=listSecrets")
```

43.8. SPRING BOOT AUTO-CONFIGURATION

The component supports 3 options, which are listed below.

Name	Description	Default	Type
camel.component.google-secret-manager.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.google-secret-manager.enabled	Whether to enable auto configuration of the google-secret-manager component. This is enabled by default.		Boolean
camel.component.google-secret-manager.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 44. GRAPHQL

Only producer is supported

The GraphQL component is a GraphQL client that communicates over HTTP and supports queries and mutations, but not subscriptions. It uses the [Apache HttpClient](#) library.

44.1. DEPENDENCIES

When using **camel-graphql** component starter with Red Hat build of Camel Spring Boot, add the following Maven dependency to your **pom.xml** to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-graphql-starter</artifactId>
</dependency>
```

44.2. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

44.2.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).
- directly in the Java code.

44.2.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

44.3. COMPONENT OPTIONS

The GraphQL component supports 2 options, which are listed below.

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

44.4. ENDPOINT OPTIONS

The GraphQL endpoint is configured using following URI syntax:

```
graphql:httpUri
```

With the following *path* and *query* parameters:

44.4.1. Path Parameters (1 parameters)

Name	Description	Default	Type
httpUri (producer)	Required The GraphQL server URI.		URI

44.4.2. Query Parameters (12 parameters)

Name	Description	Default	Type
operationName (producer)	The query or mutation name.		String
proxyHost (producer)	The proxy host in the format hostname:port.		String
query (producer)	The query text.		String
queryFile (producer)	The query file name located in the classpath.		String
queryHeader (producer)	The name of a header containing the GraphQL query.		String
variables (producer)	The JsonObject instance containing the operation variables.		JsonObject
variablesHeader (producer)	The name of a header containing a JsonObject instance containing the operation variables.		String
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
accessToken (security)	The access token sent in the Authorization header.		String
jwtAuthorizationType (security)	The JWT Authorization type. Default is Bearer.	Bearer	String
password (security)	The password for Basic authentication.		String
username (security)	The username for Basic authentication.		String

44.5. MESSAGE BODY

If the **variables** and **variablesHeader** parameters are not set and the IN body is a `JsonObject` instance, Camel uses it as the variables for the operation. If the **query** and **queryFile** parameters are not set and the IN body is a `String`, Camel uses it as the query. Camel stores the GraphQL response from the external server on the OUT message body. All headers from the IN message are copied to the OUT message, so the headers are preserved during routing. Additionally, Camel adds the HTTP response headers as well to the OUT message headers.

44.6. EXAMPLES

44.6.1. Queries

Simple queries can be defined directly in the URI:

```
from("direct:start")
  .to("graphql://http://example.com/graphql?query={books{id name}}")
```

The body can also be used for the query:

```
from("direct:start")
  .setBody(constant("{books{id name}}"))
  .to("graphql://http://example.com/graphql")
```

The query can come from a header:

```
from("direct:start")
  .setHeader("myQuery", constant("{books{id name}}"))
  .to("graphql://http://example.com/graphql?queryHeader=myQuery")
```

More complex queries can be stored in a file and referenced in the URI as follows.

booksQuery.graphql file:

```
query Books {
  books {
    id
    name
  }
}
```

```
from("direct:start")
  .to("graphql://http://example.com/graphql?queryFile=booksQuery.graphql")
```

When the query file defines multiple operations, it is required to specify which one should be executed:

```
from("direct:start")
  .to("graphql://http://example.com/graphql?
  queryFile=multipleQueries.graphql&operationName=Books")
```

Queries with variables need to reference a `JsonObject` instance from the registry:

bookByIdQuery.graphql file:

```

query BookById($id: Int!) {
  bookById(id: $id) {
    id
    name
    author
  }
}

```

```

@BindToRegistry("bookByIdQueryVariables")
public JsonObject bookByIdQueryVariables() {
  JsonObject variables = new JsonObject();
  variables.put("id", "book-1");
  return variables;
}

from("direct:start")
  .to("graphql://http://example.com/graphql?
queryFile=bookByIdQuery.graphql&variables=#bookByIdQueryVariables")

```

A query that accesses variables via the variablesHeader parameter:

```

from("direct:start")
  .setHeader("myVariables", () -> {
    JsonObject variables = new JsonObject();
    variables.put("id", "book-1");
    return variables;
  })
  .to("graphql://http://example.com/graphql?
queryFile=bookByIdQuery.graphql&variablesHeader=myVariables")

```

44.6.2. Mutations

Mutations are like queries with variables. They specify a query and a reference to a variables' bean as follows:

addBookMutation.graphql file:

```

mutation AddBook($bookInput: BookInput) {
  addBook(bookInput: $bookInput) {
    id
    name
    author {
      name
    }
  }
}

@BindToRegistry("addBookMutationVariables")
public JsonObject addBookMutationVariables() {
  JsonObject bookInput = new JsonObject();
  bookInput.put("name", "Typee");
  bookInput.put("authorId", "author-2");
  JsonObject variables = new JsonObject();
}

```

```

        variables.put("bookInput", bookInput);
        return variables;
    }

    from("direct:start")
        .to("graphql://http://example.com/graphql?
            queryFile=addBookMutation.graphql&variables=#addBookMutationVariables")

```

44.7. SPRING BOOT AUTO-CONFIGURATION

The component supports 3 options, which are listed below.

Name	Description	Default	Type
camel.component.graphql.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.graphql.enabled	Whether to enable auto configuration of the graphql component. This is enabled by default.		Boolean
camel.component.graphql.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 45. GROOVY

Since Camel 1.3

Camel has support for using [Groovy](#). For example, you can use Groovy in a [Predicate](#) with the [Message Filter](#) EIP.

45.1. DEPENDENCIES

When using **camel-groovy** with Red Hat build of Camel Spring Boot, add the following Maven dependency to your **pom.xml** to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-groovy-starter</artifactId>
</dependency>
```

45.2. URI FORMAT

The **camel-groovy** language component uses the following URI notation:

```
groovy("someGroovyExpression")
```

45.3. GROOVY OPTIONS

The Groovy language supports 2 options, which are listed below.

Name	Default	Java Type	Description
resultType		String	Sets the class of the result type (type from output).
trim	true	Boolean	Whether to trim the value to remove leading and trailing whitespaces and line breaks.

45.4. EXAMPLES

Following example uses a groovy script as predicate in the message filter, to determine if any line items are over \$100:

Java

```
from("queue:foo")
  .filter(groovy("request.lineItems.any { i -> i.value > 100 }"))
  .to("queue:bar")
```

XML DSL

```
<route>
```

```

<from uri="queue:foo"/>
<filter>
  <groovy>request.lineItems.any { i -> i.value > 100 }</groovy>
  <to uri="queue:bar"/>
</filter>
</route>

```

45.5. GROOVY CONTEXT

Camel provides an exchange information in the Groovy context (just a **Map**). The **Exchange** is transferred as:

key	value
exchange	The Exchange itself.
exchangeProperties	The Exchange properties.
variables	The variables
headers	The headers of the In message.
camelContext	The Camel Context.
request	The In message.
body	The In message body.
response	The Out message (only for InOut message exchange pattern).

45.6. HOW TO GET THE RESULT FROM MULTIPLE STATEMENTS SCRIPT

As the Groovy script engine evaluate method returns a **Null** if it runs a multiple statements script. Camel looks up the value of script result by using the key of **result** from the value set. If you have multiple statements scripts, make sure to set the value of result variable as the script return value.

```

bar = "baz";
# some other statements ...
# camel take the result value as the script evaluation result
result = body * 2 + 1

```

45.7. CUSTOMIZING GROOVY SHELL

For very special use cases you may need to use a custom **GroovyShell** instance in your Groovy expressions. To provide the custom **GroovyShell**, add an implementation of the **org.apache.camel.language.groovy.GroovyShellFactory** SPI interface to the Camel registry.

```

public class CustomGroovyShellFactory implements GroovyShellFactory {

    public GroovyShell createGroovyShell(Exchange exchange) {
        ImportCustomizer importCustomizer = new ImportCustomizer();
        importCustomizer.addStaticStars("com.example.Utills");
        CompilerConfiguration configuration = new CompilerConfiguration();
        configuration.addCompilationCustomizers(importCustomizer);
        return new GroovyShell(configuration);
    }

}

```

Camel will then use your custom GroovyShell instance (containing your custom static imports), instead of the default one.

45.8. LOADING SCRIPT FROM EXTERNAL RESOURCE

You can externalize the script and have Camel load it from a resource such as **"classpath:"**, **"file:"**, or **"http:"**. You can achieve this by using the following syntax:

```
`"resource:scheme:location"`,
```

For example, to refer to a file on the classpath you can use the following:

```
.setHeader("myHeader").groovy("resource:classpath:mygroovy.groovy")
```

45.9. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.language.groovy.enabled	Whether to enable auto configuration of the groovy language. This is enabled by default.		Boolean
camel.language.groovy.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean

CHAPTER 46. GRPC

Since Camel 2.19

Both producer and consumer are supported

The gRPC component allows you to call or expose Remote Procedure Call (RPC) services using [Protocol Buffers \(protobuf\)](#) exchange format over HTTP/2 transport.

46.1. DEPENDENCIES

When using **grpc** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-grpc-starter</artifactId>
</dependency>
```

46.2. URI FORMAT

```
grpc:host:port/service[?options]
```

46.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

46.3.1. Configuring component options

The component level is the highest level which holds general and common configurations that are inherited by the endpoints. For example a component may have security settings, credentials for authentication, urls for network connection and so forth.

Some components only have a few options, and others may have many. Because components typically have pre configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

Configuring components can be done with the [Component DSL](#), in a configuration file (application.properties|yaml), or directly with Java code.

46.3.2. Configuring endpoint options

Where you find yourself configuring the most is on endpoints, as endpoints often have many options, which allows you to configure what you need the endpoint to do. The options are also categorized into whether the endpoint is used as consumer (from) or as a producer (to), or used for both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#), which allows to not hardcode urls, port numbers, sensitive information, and other settings. In other words placeholders allows to externalize the configuration from your code, and gives more flexibility and reuse.

The following two sections lists all the options, firstly for the component followed by the endpoint.

46.4. COMPONENT OPTIONS

The gRPC component supports 3 options, which are listed below.

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

46.5. ENDPOINT OPTIONS

The gRPC endpoint is configured using URI syntax:

```
grpc:host:port/service
```

with the following path and query parameters:

46.5.1. Path Parameters (3 parameters)

Name	Description	Default	Type
host (common)	Required The gRPC server host name. This is localhost or 0.0.0.0 when being a consumer or remote server host name when using producer.		String
port (common)	Required The gRPC local or remote server port.		int
service (common)	Required Fully qualified service name from the protocol buffer descriptor file (package dot service definition name).		String

46.5.2. Query Parameters (29 parameters)

Name	Description	Default	Type
flowControlWindow (common)	The HTTP/2 flow control window size (MiB).	1048576	int
maxMessageSize (common)	The maximum message size allowed to be received/sent (MiB).	4194304	int
autoDiscoverServerInterceptors (consumer)	Setting the autoDiscoverServerInterceptors mechanism, if true, the component will look for a ServerInterceptor instance in the registry automatically otherwise it will skip that checking.	true	boolean
consumerStrategy (consumer)	This option specifies the top-level strategy for processing service requests and responses in streaming mode. If an aggregation strategy is selected, all requests will be accumulated in the list, then transferred to the flow, and the accumulated responses will be sent to the sender. If a propagation strategy is selected, request is sent to the stream, and the response will be immediately sent back to the sender. Enum values: ● AGGREGATION ● PROPAGATION	PROPAGATION	GrpcConsumerStrategy

Name	Description	Default	Type
forwardOnCompleted (consumer)	Determines if onCompleted events should be pushed to the Camel route.	false	boolean
forwardOnError (consumer)	Determines if onError events should be pushed to the Camel route. Exceptions will be set as message body.	false	boolean
maxConcurrentCallsPerConnection (consumer)	The maximum number of concurrent calls permitted for each incoming server connection.	2147483647	int
routeControlledStreamObserver (consumer)	Lets the route to take control over stream observer. If this value is set to true, then the response observer of gRPC call will be set with the name GrpcConstants.GRPC_RESPONSE_OBSERVER in the Exchange object. Please note that the stream observer's onNext(), onError(), onCompleted() methods should be called in the route.	false	boolean
bridgeErrorHandler (consumer (advanced))	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut		ExchangePattern
autoDiscoverClientInterceptors (producer)	Setting the autoDiscoverClientInterceptors mechanism, if true, the component will look for a ClientInterceptor instance in the registry automatically otherwise it will skip that checking.	true	boolean

Name	Description	Default	Type
method (producer)	gRPC method name.		String
producerStrategy (producer)	The mode used to communicate with a remote gRPC server. In SIMPLE mode a single exchange is translated into a remote procedure call. In STREAMING mode all exchanges will be sent within the same request (input and output of the recipient gRPC service must be of type 'stream'). Enum values: • SIMPLE • STREAMING	SIMPLE	GrpcProducerStrategy
streamRepliesTo (producer)	When using STREAMING client mode, it indicates the endpoint where responses should be forwarded.		String
userAgent (producer)	The user agent header passed to the server.		String
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
synchronous (advanced)	Sets whether synchronous processing should be strictly used.	false	boolean
authenticationType (security)	Authentication method type in advance to the SSL/TLS negotiation. Enum values: • NONE • GOOGLE • JWT	NONE	GrpcAuthType

Name	Description	Default	Type
jwtAlgorithm (security)	JSON Web Token sign algorithm. Enum values: • HMAC256 • HMAC384 • HMAC512	HMAC256	JwtAlgorithm
jwtIssuer (security)	JSON Web Token issuer.		String
jwtSecret (security)	JSON Web Token secret.		String
jwtSubject (security)	JSON Web Token subject.		String
keyCertChainResource (security)	The X.509 certificate chain file resource in PEM format link.		String
keyPassword (security)	The PKCS#8 private key file password.		String
keyResource (security)	The PKCS#8 private key file resource in PEM format link.		String
negotiationType (security)	Identifies the security negotiation type used for HTTP/2 communication. Enum values: • TLS • PLAINTEXT_UPGRADE • PLAINTEXT	PLAINTEXT	NegotiationType
serviceAccountResource (security)	Service Account key file in JSON format resource link supported by the Google Cloud SDK.		String
trustCertCollectionResource (security)	The trusted certificates collection file resource in PEM format for verifying the remote endpoint's certificate.		String

46.6. MESSAGE HEADERS

The gRPC component supports 3 message header(s), which is/are listed below:

Name	Description	Default	Type
CamelGrpcMethod dName (consumer) Constant: GRPC_METHOD_NAME_HEADER	Method name handled by the consumer service.		String
CamelGrpcUserAgent (consumer) Constant: GRPC_USER_AGENT_HEADER	If provided, the given agent will prepend the gRPC library's user agent information.		String
CamelGrpcEventType (consumer) Constant: GRPC_EVENT_TYPE_HEADER	Received event type from the sent request. Possible values: onNext onCompleted onError.		String

46.7. TRANSPORT SECURITY AND AUTHENTICATION SUPPORT

The following [authentication](#) mechanisms are built-in to gRPC and available in this component:

- **SSL/TLS:** gRPC has SSL/TLS integration and promotes the use of SSL/TLS to authenticate the server, and to encrypt all the data exchanged between the client and the server. Optional mechanisms are available for clients to provide certificates for mutual authentication.
- **Token-based authentication with Google:** gRPC provides a generic mechanism to attach metadata based credentials to requests and responses. Additional support for acquiring access tokens while accessing Google APIs through gRPC is provided. In general this mechanism must be used as well as SSL/TLS on the channel.

To enable these features the following component properties combinations must be configured:

Num.	Option	Parameter	Value	Required/Optional
1	SSL/TLS	negotiationType	TLS	Required
		keyCertChainResource		Required
		keyResource		Required
		keyPassword		Optional

Num.	Option	Parameter	Value	Required/Optional
		trustCertCollectionResource		Optional
2	Token-based authentication with Google API	authenticationType	GOOGLE	Required
		negotiationType	TLS	Required
		serviceAccountResource		Required
3	Custom JSON Web Token implementation authentication	authenticationType	JWT	Required
		negotiationType	NONE or TLS	Optional. The TLS/SSL not checking for this type, but strongly recommended.
		jwtAlgorithm	HMAC256(default) or (HMAC384, HMAC512)	Optional
		jwtSecret		Required
		jwtIssuer		Optional
		jwtSubject		Optional

46.8. GRPC PRODUCER RESOURCE TYPE MAPPING

The table below shows the types of objects in the message body, depending on the types (simple or stream) of incoming and outgoing parameters, as well as the invocation style (synchronous or asynchronous). Please note, that invocation of the procedures with incoming stream parameter in asynchronous style are not allowed.

Invocation style	Request type	Response type	Request Body Type	Result Body Type
synchronous	simple	simple	Object	Object
synchronous	simple	stream	Object	List<Object>

Invocation style	Request type	Response type	Request Body Type	Result Body Type
synchronous	stream	simple	not allowed	not allowed
synchronous	stream	stream	not allowed	not allowed
asynchronous	simple	simple	Object	List<Object>
asynchronous	simple	stream	Object	List<Object>
asynchronous	stream	simple	Object or List<Object>	List<Object>
asynchronous	stream	stream	Object or List<Object>	List<Object>

46.9. EXAMPLES

Below is a simple synchronous method invoke with host and port parameters:

```
from("direct:grpc-sync")
.to("grpc://remotehost:1101/org.apache.camel.component.grpc.PingPong?
method=sendPing&synchronous=true");

<route>
  <from uri="direct:grpc-sync" />
  <to uri="grpc://remotehost:1101/org.apache.camel.component.grpc.PingPong?
method=sendPing&synchronous=true"/>
</route>
```

An asynchronous method invokes

```
from("direct:grpc-async")
.to("grpc://remotehost:1101/org.apache.camel.component.grpc.PingPong?
method=pingAsyncResponse");
```

a gRPC service consumer with propagation consumer strategy:

```
from("grpc://localhost:1101/org.apache.camel.component.grpc.PingPong?
consumerStrategy=PROPAGATION")
.to("direct:grpc-service");
```

gRPC service producer with streaming producer strategy (requires a service that uses "stream" mode as input and output):

```
from("direct:grpc-request-stream")
.to("grpc://remotehost:1101/org.apache.camel.component.grpc.PingPong?
method=PingAsyncAsync&producerStrategy=STREAMING&streamRepliesTo=direct:grpc-response-stream");
```

```
from("direct:grpc-response-stream")
.log("Response received: ${body}");
```

gRPC service consumer TLS/SSL security negotiation enabled:

```
from("grpc://localhost:1101/org.apache.camel.component.grpc.PingPong?
consumerStrategy=PROPAGATION&negotiationType=TLS&keyCertChainResource=file:src/test/resour
ces/certs/server.pem&keyResource=file:src/test/resources/certs/server.key&trustCertCollectionResource
=file:src/test/resources/certs/ca.pem")
.to("direct:tls-enable")
```

gRPC service producer with custom JSON Web Token (JWT) implementation authentication:

```
from("direct:grpc-jwt")
.to("grpc://localhost:1101/org.apache.camel.component.grpc.PingPong?
method=pingSyncSync&synchronous=true&authenticationType=JWT&jwtSecret=supersecuredsecret"
);
```

46.10. CONFIGURATION

Use the **protobuf-maven-plugin**, which calls the Protocol Buffer Compiler (protoc) to generate Java source files from .proto (protocol buffer definition) files. This plugin will generate procedures request and response classes, their builders and gRPC procedures stubs classes as well.

Following steps are required:

Insert operating system and CPU architecture detection extension inside **<build>** tag of the project pom.xml or set `${os.detected.classifier}` parameter manually

```
<extensions>
<extension>
<groupId>kr.motd.maven</groupId>
<artifactId>os-maven-plugin</artifactId>
<version>1.7.1</version>
</extension>
</extensions>
```

Insert the gRPC and protobuf Java code generator plugins into the **<plugins>** tag of the project's pom.xml.

```
<plugin>
<groupId>org.xolstice.maven.plugins</groupId>
<artifactId>protobuf-maven-plugin</artifactId>
<version>0.6.1</version>
<configuration>
<protocArtifact>com.google.protobuf:protoc:${protobuf-
version}:exe:${os.detected.classifier}</protocArtifact>
<pluginId>grpc-java</pluginId>
<pluginArtifact>io.grpc:protoc-gen-grpc-java:${grpc-
version}:exe:${os.detected.classifier}</pluginArtifact>
</configuration>
<executions>
<execution>
```

```

    <goals>
    <goal>compile</goal>
    <goal>compile-custom</goal>
    <goal>test-compile</goal>
    <goal>test-compile-custom</goal>
    </goals>
  </execution>
</executions>
</plugin>

```

46.11. ADDITIONAL RESOURCES

See these resources:

- [gRPC project site](#)
- [Maven Protocol Buffers Plugin](#)

46.12. SPRING BOOT AUTO-CONFIGURATION

The component supports 4 options, which are listed below.

Name	Description	Default	Type
camel.component.grpc.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.grpc.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.grpc.enabled	Whether to enable auto configuration of the grpc component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.grpc.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 47. HEADER

The Header Expression Language allows you to extract values of named headers.

47.1. DEPENDENCIES

The Header language is part of **camel-core**.

When using **header** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-core-starter</artifactId>
</dependency>
```

47.2. HEADER OPTIONS

The Header language supports 1 options, which are listed below.

Name	Default	Java Type	Description
trim		Boolean	Whether to trim the value to remove leading and trailing whitespaces and line breaks.

47.3. EXAMPLE USAGE

The **recipientList** EIP can utilize a header:

```
<route>
  <from uri="direct:a" />
  <recipientList>
    <header>myHeader</header>
  </recipientList>
</route>
```

In this case, the list of recipients are contained in the header 'myHeader'.

And the same example in Java DSL:

```
from("direct:a").recipientList(header("myHeader"));
```

47.4. SPRING BOOT AUTO-CONFIGURATION

The component supports 147 options, which are listed below.

Name	Description	Default	Type
<code>camel.cloud.consul.service-discovery.acl-token</code>	Sets the ACL token to be used with Consul.		String
<code>camel.cloud.consul.service-discovery.block-seconds</code>	The seconds to wait for a watch event, default 10 seconds.	10	Integer
<code>camel.cloud.consul.service-discovery.configurations</code>	Define additional configuration definitions.		Map
<code>camel.cloud.consul.service-discovery.connect-timeout-millis</code>	Connect timeout for OkHttpClient.		Long
<code>camel.cloud.consul.service-discovery.datacenter</code>	The data center.		String
<code>camel.cloud.consul.service-discovery.enabled</code>	Enable the component.	true	Boolean
<code>camel.cloud.consul.service-discovery.password</code>	Sets the password to be used for basic authentication.		String
<code>camel.cloud.consul.service-discovery.properties</code>	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in <code>com.netflix.client.config.CommonClientConfigKey</code> .		Map
<code>camel.cloud.consul.service-discovery.read-timeout-millis</code>	Read timeout for OkHttpClient.		Long
<code>camel.cloud.consul.service-discovery.url</code>	The Consul agent URL.		String

Name	Description	Default	Type
<code>camel.cloud.consul.service-discovery.username</code>	Sets the username to be used for basic authentication.		String
<code>camel.cloud.consul.service-discovery.write-timeout-millis</code>	Write timeout for OkHttpClient.		Long
<code>camel.cloud.dns.service-discovery.configurations</code>	Define additional configuration definitions.		Map
<code>camel.cloud.dns.service-discovery.domain</code>	The domain name;.		String
<code>camel.cloud.dns.service-discovery.enabled</code>	Enable the component.	true	Boolean
<code>camel.cloud.dns.service-discovery.properties</code>	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in <code>com.netflix.client.config.CommonClientConfigKey</code> .		Map
<code>camel.cloud.dns.service-discovery.proto</code>	The transport protocol of the desired service.	<code>_tcp</code>	String
<code>camel.cloud.etcd.service-discovery.configurations</code>	Define additional configuration definitions.		Map
<code>camel.cloud.etcd.service-discovery.enabled</code>	Enable the component.	true	Boolean
<code>camel.cloud.etcd.service-discovery.password</code>	The password to use for basic authentication.		String

Name	Description	Default	Type
<code>camel.cloud.etcd.service-discovery.properties</code>	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in <code>com.netflix.client.config.CommonClientConfigKey</code> .		Map
<code>camel.cloud.etcd.service-discovery.service-path</code>	The path to look for for service discovery.	<code>/services/</code>	String
<code>camel.cloud.etcd.service-discovery.timeout</code>	To set the maximum time an action could take to complete.		Long
<code>camel.cloud.etcd.service-discovery.type</code>	To set the discovery type, valid values are on-demand and watch.	on-demand	String
<code>camel.cloud.etcd.service-discovery.uris</code>	The URIs the client can connect to.		String
<code>camel.cloud.etcd.service-discovery.user-name</code>	The user name to use for basic authentication.		String
<code>camel.cloud.kubernetes.service-discovery.api-version</code>	Sets the API version when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.ca-cert-data</code>	Sets the Certificate Authority data when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.ca-cert-file</code>	Sets the Certificate Authority data that are loaded from the file when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.client-cert-data</code>	Sets the Client Certificate data when using client lookup.		String

Name	Description	Default	Type
<code>camel.cloud.kubernetes.service-discovery.client-cert-file</code>	Sets the Client Certificate data that are loaded from the file when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.client-key-algo</code>	Sets the Client Keystore algorithm, such as RSA when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.client-key-data</code>	Sets the Client Keystore data when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.client-key-file</code>	Sets the Client Keystore data that are loaded from the file when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.client-key-passphrase</code>	Sets the Client Keystore passphrase when using client lookup.		String
<code>camel.cloud.kubernetes.service-discovery.configurations</code>	Define additional configuration definitions.		Map
<code>camel.cloud.kubernetes.service-discovery.dns-domain</code>	Sets the DNS domain to use for DNS lookup.		String
<code>camel.cloud.kubernetes.service-discovery.enabled</code>	Enable the component.	true	Boolean

Name	Description	Default	Type
camel.cloud.kubernetes.service-discovery.lookup	How to perform service lookup. Possible values: client, dns, environment. When using client, then the client queries the kubernetes master to obtain a list of active pods that provides the service, and then random (or round robin) select a pod. When using dns the service name is resolved as name.namespace.svc.dnsDomain. When using dnssrv the service name is resolved with SRV query forsvc... When using environment then environment variables are used to lookup the service. By default environment is used.	environment	String
camel.cloud.kubernetes.service-discovery.master-url	Sets the URL to the master when using client lookup.		String
camel.cloud.kubernetes.service-discovery.namespace	Sets the namespace to use. Will by default use namespace from the ENV variable KUBERNETES_MASTER.		String
camel.cloud.kubernetes.service-discovery.oauth-token	Sets the OAUTH token for authentication (instead of username/password) when using client lookup.		String
camel.cloud.kubernetes.service-discovery.password	Sets the password for authentication when using client lookup.		String
camel.cloud.kubernetes.service-discovery.port-name	Sets the Port Name to use for DNS/DNSSRV lookup.		String
camel.cloud.kubernetes.service-discovery.port-protocol	Sets the Port Protocol to use for DNS/DNSSRV lookup.		String
camel.cloud.kubernetes.service-discovery.properties	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in com.netflix.client.config.CommonClientConfigKey.		Map

Name	Description	Default	Type
<code>camel.cloud.kubernetes.service-discovery.trust-certs</code>	Sets whether to turn on trust certificate check when using client lookup.	false	Boolean
<code>camel.cloud.kubernetes.service-discovery.username</code>	Sets the username for authentication when using client lookup.		String
<code>camel.cloud.ribbon.load-balancer.client-name</code>	Sets the Ribbon client name.		String
<code>camel.cloud.ribbon.load-balancer.configurations</code>	Define additional configuration definitions.		Map
<code>camel.cloud.ribbon.load-balancer.enabled</code>	Enable the component.	true	Boolean
<code>camel.cloud.ribbon.load-balancer.namespace</code>	The namespace.		String
<code>camel.cloud.ribbon.load-balancer.password</code>	The password.		String
<code>camel.cloud.ribbon.load-balancer.properties</code>	Set client properties to use. These properties are specific to what service call implementation are in use. For example if using ribbon, then the client properties are define in <code>com.netflix.client.config.CommonClientConfigKey</code> .		Map
<code>camel.cloud.ribbon.load-balancer.username</code>	The username.		String

Name	Description	Default	Type
camel.hystrix.allow-maximum-size-to-diverge-from-core-size	Allows the configuration for <code>maximumSize</code> to take effect. That value can then be equal to, or higher, than <code>coreSize</code> .	false	Boolean
camel.hystrix.circuit-breaker-enabled	Whether to use a <code>HystrixCircuitBreaker</code> or not. If false no circuit-breaker logic will be used and all requests permitted. This is similar in effect to <code>circuitBreakerForceClosed()</code> except that continues tracking metrics and knowing whether it should be open/closed, this property results in not even instantiating a circuit-breaker.	true	Boolean
camel.hystrix.circuit-breaker-error-threshold-percentage	Error percentage threshold (as whole number such as 50) at which point the circuit breaker will trip open and reject requests. It will stay tripped for the duration defined in <code>circuitBreakerSleepWindowInMilliseconds</code> ; The error percentage this is compared against comes from <code>HystrixCommandMetrics.getHealthCounts()</code> .	50	Integer
camel.hystrix.circuit-breaker-force-closed	If true the <code>HystrixCircuitBreaker#allowRequest()</code> will always return true to allow requests regardless of the error percentage from <code>HystrixCommandMetrics.getHealthCounts()</code> . The <code>circuitBreakerForceOpen()</code> property takes precedence so if it set to true this property does nothing.	false	Boolean
camel.hystrix.circuit-breaker-force-open	If true the <code>HystrixCircuitBreaker.allowRequest()</code> will always return false, causing the circuit to be open (tripped) and reject all requests. This property takes precedence over <code>circuitBreakerForceClosed()</code> ;	false	Boolean
camel.hystrix.circuit-breaker-request-volume-threshold	Minimum number of requests in the <code>metricsRollingStatisticalWindowInMilliseconds()</code> that must exist before the <code>HystrixCircuitBreaker</code> will trip. If below this number the circuit will not trip regardless of error percentage.	20	Integer
camel.hystrix.circuit-breaker-sleep-window-in-milliseconds	The time in milliseconds after a <code>HystrixCircuitBreaker</code> trips open that it should wait before trying requests again.	5000	Integer

Name	Description	Default	Type
camel.hystrix.configurations	Define additional configuration definitions.		Map
camel.hystrix.core-pool-size	Core thread-pool size that gets passed to <code>java.util.concurrent.ThreadPoolExecutor#setCorePoolSize(int)</code> .	10	Integer
camel.hystrix.enabled	Enable the component.	true	Boolean
camel.hystrix.execution-isolation-semaphore-max-concurrent-requests	Number of concurrent requests permitted to <code>HystrixCommand.run()</code> . Requests beyond the concurrent limit will be rejected. Applicable only when <code>executionIsolationStrategy == SEMAPHORE</code> .	20	Integer
camel.hystrix.execution-isolation-strategy	What isolation strategy <code>HystrixCommand.run()</code> will be executed with. If <code>THREAD</code> then it will be executed on a separate thread and concurrent requests limited by the number of threads in the thread-pool. If <code>SEMAPHORE</code> then it will be executed on the calling thread and concurrent requests limited by the semaphore count.	THREAD	String
camel.hystrix.execution-isolation-thread-interrupt-on-timeout	Whether the execution thread should attempt an interrupt (using <code>Future#cancel()</code>) when a thread times out. Applicable only when <code>executionIsolationStrategy() == THREAD</code> .	true	Boolean
camel.hystrix.execution-timeout-enabled	Whether the timeout mechanism is enabled for this command.	true	Boolean
camel.hystrix.execution-timeout-in-milliseconds	Time in milliseconds at which point the command will timeout and halt execution. If <code>executionIsolationThreadInterruptOnTimeout == true</code> and the command is thread-isolated, the executing thread will be interrupted. If the command is semaphore-isolated and a <code>HystrixObservableCommand</code> , that command will get unsubscribed.	1000	Integer
camel.hystrix.fallback-enabled	Whether <code>HystrixCommand.getFallback()</code> should be attempted when failure occurs.	true	Boolean

Name	Description	Default	Type
camel.hystrix.fallback-isolation-semaphore-max-concurrent-requests	Number of concurrent requests permitted to <code>HystrixCommand.getFallback()</code> . Requests beyond the concurrent limit will fail-fast and not attempt retrieving a fallback.	10	Integer
camel.hystrix.group-key	Sets the group key to use. The default value is <code>CamelHystrix</code> .	CamelHystrix	String
camel.hystrix.keep-alive-time	Keep-alive time in minutes that gets passed to <code>ThreadPoolExecutor#setKeepAliveTime(long, TimeUnit)</code> .	1	Integer
camel.hystrix.max-queue-size	Max queue size that gets passed to <code>BlockingQueue</code> in <code>HystrixConcurrencyStrategy.getBlockingQueue(int)</code> . This should only affect the instantiation of a threadpool - it is not eligible to change a queue size on the fly. For that, use <code>queueSizeRejectionThreshold()</code> .	-1	Integer
camel.hystrix.maximum-size	Maximum thread-pool size that gets passed to <code>ThreadPoolExecutor#setMaximumPoolSize(int)</code> . This is the maximum amount of concurrency that can be supported without starting to reject <code>HystrixCommands</code> . Please note that this setting only takes effect if you also set <code>allowMaximumSizeToDivergeFromCoreSize</code> .	10	Integer
camel.hystrix.metrics-health-snapshot-interval-in-milliseconds	Time in milliseconds to wait between allowing health snapshots to be taken that calculate success and error percentages and affect <code>HystrixCircuitBreaker.isOpen()</code> status. On high-volume circuits the continual calculation of error percentage can become CPU intensive thus this controls how often it is calculated.	500	Integer
camel.hystrix.metrics-rolling-percentile-bucket-size	Maximum number of values stored in each bucket of the rolling percentile. This is passed into <code>HystrixRollingPercentile</code> inside <code>HystrixCommandMetrics</code> .	10	Integer
camel.hystrix.metrics-rolling-percentile-enabled	Whether percentile metrics should be captured using <code>HystrixRollingPercentile</code> inside <code>HystrixCommandMetrics</code> .	true	Boolean

Name	Description	Default	Type
camel.hystrix.metrics-rolling-percentile-window-buckets	Number of buckets the rolling percentile window is broken into. This is passed into HystrixRollingPercentile inside HystrixCommandMetrics.	6	Integer
camel.hystrix.metrics-rolling-percentile-window-in-milliseconds	Duration of percentile rolling window in milliseconds. This is passed into HystrixRollingPercentile inside HystrixCommandMetrics.	10000	Integer
camel.hystrix.metrics-rolling-statistical-window-buckets	Number of buckets the rolling statistical window is broken into. This is passed into HystrixRollingNumber inside HystrixCommandMetrics.	10	Integer
camel.hystrix.metrics-rolling-statistical-window-in-milliseconds	This property sets the duration of the statistical rolling window, in milliseconds. This is how long metrics are kept for the thread pool. The window is divided into buckets and rolls by those increments.	10000	Integer
camel.hystrix.queue-size-rejection-threshold	Queue size rejection threshold is an artificial max size at which rejections will occur even if maxQueueSize has not been reached. This is done because the maxQueueSize of a BlockingQueue can not be dynamically changed and we want to support dynamically changing the queue size that affects rejections. This is used by HystrixCommand when queuing a thread for execution.	5	Integer
camel.hystrix.request-log-enabled	Whether HystrixCommand execution and events should be logged to HystrixRequestLog.	true	Boolean
camel.hystrix.thread-pool-key	Sets the thread pool key to use. Will by default use the same value as groupKey has been configured to use.	Camel Hystrix	String
camel.hystrix.thread-pool-rolling-number-statistical-window-buckets	Number of buckets the rolling statistical window is broken into. This is passed into HystrixRollingNumber inside each HystrixThreadPoolMetrics instance.	10	Integer

Name	Description	Default	Type
camel.hystrix.thread-pool-rolling-number-statistical-window-in-milliseconds	Duration of statistical rolling window in milliseconds. This is passed into HystrixRollingNumber inside each HystrixThreadPoolMetrics instance.	10000	Integer
camel.language.constant.enabled	Whether to enable auto configuration of the constant language. This is enabled by default.		Boolean
camel.language.constant.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
camel.language.csimple.enabled	Whether to enable auto configuration of the csimple language. This is enabled by default.		Boolean
camel.language.csimple.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
camel.language.exchangeproperty.enabled	Whether to enable auto configuration of the exchangeProperty language. This is enabled by default.		Boolean
camel.language.exchangeproperty.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
camel.language.file.enabled	Whether to enable auto configuration of the file language. This is enabled by default.		Boolean
camel.language.file.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
camel.language.header.enabled	Whether to enable auto configuration of the header language. This is enabled by default.		Boolean
camel.language.header.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
camel.language.ref.enabled	Whether to enable auto configuration of the ref language. This is enabled by default.		Boolean
camel.language.ref.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean

Name	Description	Default	Type
<code>camel.language.simple.enabled</code>	Whether to enable auto configuration of the simple language. This is enabled by default.		Boolean
<code>camel.language.simple.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
<code>camel.language.tokenize.enabled</code>	Whether to enable auto configuration of the tokenize language. This is enabled by default.		Boolean
<code>camel.language.tokenize.group-delimiter</code>	Sets the delimiter to use when grouping. If this has not been set then token will be used as the delimiter.		String
<code>camel.language.tokenize.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
<code>camel.resilience4j.automatic-transition-from-open-to-half-open-enabled</code>	Enables automatic transition from OPEN to HALF_OPEN state once the <code>waitDurationInOpenState</code> has passed.	false	Boolean
<code>camel.resilience4j.circuit-breaker-ref</code>	Refers to an existing <code>io.github.resilience4j.circuitbreaker.CircuitBreaker</code> instance to lookup and use from the registry. When using this, then any other circuit breaker options are not in use.		String
<code>camel.resilience4j.config-ref</code>	Refers to an existing <code>io.github.resilience4j.circuitbreaker.CircuitBreakerConfig</code> instance to lookup and use from the registry.		String
<code>camel.resilience4j.configurations</code>	Define additional configuration definitions.		Map
<code>camel.resilience4j.enabled</code>	Enable the component.	true	Boolean
<code>camel.resilience4j.failure-rate-threshold</code>	Configures the failure rate threshold in percentage. If the failure rate is equal or greater than the threshold the <code>CircuitBreaker</code> transitions to open and starts short-circuiting calls. The threshold must be greater than 0 and not greater than 100. Default value is 50 percentage.		Float

Name	Description	Default	Type
camel.resilience4j.minimum-number-of-calls	Configures the minimum number of calls which are required (per sliding window period) before the CircuitBreaker can calculate the error rate. For example, if <code>minimumNumberOfCalls</code> is 10, then at least 10 calls must be recorded, before the failure rate can be calculated. If only 9 calls have been recorded the CircuitBreaker will not transition to open even if all 9 calls have failed. Default <code>minimumNumberOfCalls</code> is 100.	100	Integer
camel.resilience4j.permitted-number-of-calls-in-half-open-state	Configures the number of permitted calls when the CircuitBreaker is half open. The size must be greater than 0. Default size is 10.	10	Integer
camel.resilience4j.sliding-window-size	Configures the size of the sliding window which is used to record the outcome of calls when the CircuitBreaker is closed. <code>slidingWindowSize</code> configures the size of the sliding window. Sliding window can either be count-based or time-based. If <code>slidingWindowType</code> is <code>COUNT_BASED</code> , the last <code>slidingWindowSize</code> calls are recorded and aggregated. If <code>slidingWindowType</code> is <code>TIME_BASED</code> , the calls of the last <code>slidingWindowSize</code> seconds are recorded and aggregated. The <code>slidingWindowSize</code> must be greater than 0. The <code>minimumNumberOfCalls</code> must be greater than 0. If the <code>slidingWindowType</code> is <code>COUNT_BASED</code> , the <code>minimumNumberOfCalls</code> cannot be greater than <code>slidingWindowSize</code> . If the <code>slidingWindowType</code> is <code>TIME_BASED</code> , you can pick whatever you want. Default <code>slidingWindowSize</code> is 100.	100	Integer
camel.resilience4j.sliding-window-type	Configures the type of the sliding window which is used to record the outcome of calls when the CircuitBreaker is closed. Sliding window can either be count-based or time-based. If <code>slidingWindowType</code> is <code>COUNT_BASED</code> , the last <code>slidingWindowSize</code> calls are recorded and aggregated. If <code>slidingWindowType</code> is <code>TIME_BASED</code> , the calls of the last <code>slidingWindowSize</code> seconds are recorded and aggregated. Default <code>slidingWindowType</code> is <code>COUNT_BASED</code> .	COUNT_BASED	String
camel.resilience4j.slow-call-duration-threshold	Configures the duration threshold (seconds) above which calls are considered as slow and increase the slow calls percentage. Default value is 60 seconds.	60	Integer

Name	Description	Default	Type
camel.resilience4j.slow-call-rate-threshold	Configures a threshold in percentage. The CircuitBreaker considers a call as slow when the call duration is greater than <code>slowCallDurationThreshold</code> Duration. When the percentage of slow calls is equal or greater the threshold, the CircuitBreaker transitions to open and starts short-circuiting calls. The threshold must be greater than 0 and not greater than 100. Default value is 100 percentage which means that all recorded calls must be slower than <code>slowCallDurationThreshold</code> .		Float
camel.resilience4j.wait-duration-in-open-state	Configures the wait duration (in seconds) which specifies how long the CircuitBreaker should stay open, before it switches to half open. Default value is 60 seconds.	60	Integer
camel.resilience4j.writable-stack-trace-enabled	Enables writable stack traces. When set to false, <code>Exception.getStackTrace</code> returns a zero length array. This may be used to reduce log spam when the circuit breaker is open as the cause of the exceptions is already known (the circuit breaker is short-circuiting calls).	true	Boolean
camel.rest.api-component	The name of the Camel component to use as the REST API (such as swagger) If no API Component has been explicit configured, then Camel will lookup if there is a Camel component responsible for servicing and generating the REST API documentation, or if a <code>org.apache.camel.spi.RestApiProcessorFactory</code> is registered in the registry. If either one is found, then that is being used.		String
camel.rest.api-context-path	Sets a leading API context-path the REST API services will be using. This can be used when using components such as <code>camel-servlet</code> where the deployed web application is deployed using a context-path.		String
camel.rest.api-context-route-id	Sets the route id to use for the route that services the REST API. The route will by default use an auto assigned route id.		String
camel.rest.api-host	To use an specific hostname for the API documentation (eg swagger) This can be used to override the generated host with this configured hostname.		String

Name	Description	Default	Type
camel.rest.api-property	Allows to configure as many additional properties for the api documentation (swagger). For example set property api.title to my cool stuff.		Map
camel.rest.api-vendor-extension	Whether vendor extension is enabled in the Rest APIs. If enabled then Camel will include additional information as vendor extension (eg keys starting with x-) such as route ids, class names etc. Not all 3rd party API gateways and tools supports vendor-extensions when importing your API docs.	false	Boolean
camel.rest.binding-mode	Sets the binding mode to use. The default value is off.		RestBindingMode
camel.rest.client-request-validation	Whether to enable validation of the client request to check whether the Content-Type and Accept headers from the client is supported by the Rest-DSL configuration of its consumes/produces settings. This can be turned on, to enable this check. In case of validation error, then HTTP Status codes 415 or 406 is returned. The default value is false.	false	Boolean
camel.rest.component	The Camel Rest component to use for the REST transport (consumer), such as netty-http, jetty, servlet, undertow. If no component has been explicit configured, then Camel will lookup if there is a Camel component that integrates with the Rest DSL, or if a org.apache.camel.spi.RestConsumerFactory is registered in the registry. If either one is found, then that is being used.		String
camel.rest.component-property	Allows to configure as many additional properties for the rest component in use.		Map
camel.rest.consumer-property	Allows to configure as many additional properties for the rest consumer in use.		Map
camel.rest.context-path	Sets a leading context-path the REST services will be using. This can be used when using components such as camel-servlet where the deployed web application is deployed using a context-path. Or for components such as camel-jetty or camel-netty-http that includes a HTTP server.		String
camel.rest.cors-headers	Allows to configure custom CORS headers.		Map

Name	Description	Default	Type
camel.rest.data-format-property	Allows to configure as many additional properties for the data formats in use. For example set property prettyPrint to true to have json outputted in pretty mode. The properties can be prefixed to denote the option is only for either JSON or XML and for either the IN or the OUT. The prefixes are: json.in. json.out. xml.in. xml.out. For example a key with value xml.out.mustBeJAXBElement is only for the XML data format for the outgoing. A key without a prefix is a common key for all situations.		Map
camel.rest.enable-cors	Whether to enable CORS headers in the HTTP response. The default value is false.	false	Boolean
camel.rest.endpoint-property	Allows to configure as many additional properties for the rest endpoint in use.		Map
camel.rest.host	The hostname to use for exposing the REST service.		String
camel.rest.host-name-resolver	If no hostname has been explicit configured, then this resolver is used to compute the hostname the REST service will be using.		RestHostNameResolver
camel.rest.json-data-format	Name of specific json data format to use. By default json-jackson will be used. Important: This option is only for setting a custom name of the data format, not to refer to an existing data format instance.		String
camel.rest.port	The port number to use for exposing the REST service. Notice if you use servlet component then the port number configured here does not apply, as the port number in use is the actual port number the servlet component is using. eg if using Apache Tomcat its the tomcat http port, if using Apache Karaf its the HTTP service in Karaf that uses port 8181 by default etc. Though in those situations setting the port number here, allows tooling and JMX to know the port number, so its recommended to set the port number to the number that the servlet engine uses.		String

Name	Description	Default	Type
camel.rest.producer-api-doc	Sets the location of the api document (swagger api) the REST producer will use to validate the REST uri and query parameters are valid accordingly to the api document. This requires adding camel-swagger-java to the classpath, and any miss configuration will let Camel fail on startup and report the error(s). The location of the api document is loaded from classpath by default, but you can use file: or http: to refer to resources to load from file or http url.		String
camel.rest.producer-component	Sets the name of the Camel component to use as the REST producer.		String
camel.rest.scheme	The scheme to use for exposing the REST service. Usually http or https is supported. The default value is http.		String
camel.rest.skip-binding-on-error-code	Whether to skip binding on output if there is a custom HTTP error code header. This allows to build custom error messages that do not bind to json / xml etc, as success messages otherwise will do.	false	Boolean
camel.rest.use-x-forward-headers	Whether to use X-Forward headers for Host and related setting. The default value is true.	true	Boolean
camel.rest.xml-data-format	Name of specific XML data format to use. By default jaxb will be used. Important: This option is only for setting a custom name of the data format, not to refer to an existing data format instance.		String
camel.rest.api-context-id-pattern	Deprecated Sets an CamelContext id pattern to only allow Rest APIs from rest services within CamelContext's which name matches the pattern. The pattern name refers to the CamelContext name, to match on the current CamelContext only. For any other value, the pattern uses the rules from PatternHelper#matchPattern(String,String).		String
camel.rest.api-context-listing	Deprecated Sets whether listing of all available CamelContext's with REST services in the JVM is enabled. If enabled it allows to discover these contexts, if false then only the current CamelContext is in use.	false	Boolean

CHAPTER 48. HL7

The HL7 component is used for working with the HL7 MLLP protocol and [HL7 v2 messages](#) using the [HAPI library](#).

This component supports the following:

- HL7 MLLP codec for [Mina](#)
- HL7 MLLP codec for [Netty](#)
- Type Converter from/to HAPI and String
- HL7 DataFormat using the HAPI library

48.1. DEPENDENCIES

When using **hl7** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-hl7-starter</artifactId>
</dependency>
```

48.2. HL7 MLLP PROTOCOL

HL7 is often used with the HL7 MLLP protocol, which is a text based TCP socket based protocol. This component ships with a Mina and Netty Codec that conforms to the MLLP protocol so you can easily expose an HL7 listener accepting HL7 requests over the TCP transport layer. To expose a HL7 listener service, the [camel-mina](#) or link:[camel-netty](#) component is used with the HL7MLLPCodec (mina) or HL7MLLPNettyDecoder/HL7MLLPNettyEncoder (Netty).

HL7 MLLP codec can be configured as follows:

Name	Default Value	Description
startByte	0x0b	The start byte spanning the HL7 payload.
endByte1	0x1c	The first end byte spanning the HL7 payload.
endByte2	0x0d	The 2nd end byte spanning the HL7 payload.
charset	JVM Default	The encoding (a charset name) to use for the codec. If not provided, Camel will use the JVM default Charset .
produceString	true	If true, the codec creates a string using the defined charset. If false, the codec sends a plain byte array into the route, so that the HL7 Data Format can determine the actual charset from the HL7 message content.

Name	Default Value	Description
convertLFtoCR	false	Will convert \n to \r (0x0d, 13 decimal) as HL7 stipulates \r as segment terminators. The HAPI library requires the use of \r .

48.2.1. Exposing an HL7 listener using Mina

In the Spring XML file, we configure a mina endpoint to listen for HL7 requests using TCP on port **8888**:

```
<endpoint id="hl7MinaListener" uri="mina:tcp://localhost:8888?sync=true&codec=#hl7codec"/>
```

sync=true indicates that this listener is synchronous and therefore will return a HL7 response to the caller. The HL7 codec is setup with **codec=#hl7codec**. Note that **hl7codec** is just a Spring bean ID, so it could be named **mygreatcodecforhl7** or whatever. The codec is also set up in the Spring XML file:

```
<bean id="hl7codec" class="org.apache.camel.component.hl7.HL7MLLPCodec">
  <property name="charset" value="iso-8859-1"/>
</bean>
```

The endpoint **hl7MinaListener** can then be used in a route as a consumer, as this Java DSL example illustrates:

```
from("hl7MinaListener")
  .bean("patientLookupService");
```

This is a very simple route that will listen for HL7 and route it to a service named **patientLookupService**. This is also Spring bean ID, configured in the Spring XML as:

```
<bean id="patientLookupService"
class="com.mycompany.healthcare.service.PatientLookupService"/>
```

The business logic can be implemented in POJO classes that do not depend on Camel, as shown here:

```
import ca.uhn.hl7v2.HL7Exception;
import ca.uhn.hl7v2.model.Message;
import ca.uhn.hl7v2.model.v24.segment.QRD;

public class PatientLookupService {
  public Message lookupPatient(Message input) throws HL7Exception {
    QRD qrd = (QRD)input.get("QRD");
    String patientId = qrd.getWhoSubjectFilter(0).getIDNumber().getValue();

    // find patient data based on the patient id and create a HL7 model object with the response
    Message response = ... create and set response data
    return response
  }
}
```

48.2.2. Exposing an HL7 listener using Netty (available from Camel 2.15 onwards)

In the Spring XML file, we configure a netty endpoint to listen for HL7 requests using TCP on port **8888**:

```
<endpoint id="hl7NettyListener" uri="netty:tcp://localhost:8888?
sync=true&encoders=#hl7encoder&decoders=#hl7decoder"/>
```

sync=true indicates that this listener is synchronous and therefore will return a HL7 response to the caller. The HL7 codec is setup with **encoders=#hl7encoder*and*decoders=#hl7decoder**. Note that **hl7encoder** and **hl7decoder** are just bean IDs, so they could be named differently. The beans can be set in the Spring XML file:

```
<bean id="hl7decoder" class="org.apache.camel.component.hl7.HL7MLLPNettyDecoderFactory"/>
<bean id="hl7encoder" class="org.apache.camel.component.hl7.HL7MLLPNettyEncoderFactory"/>
```

The endpoint **hl7NettyListener** can then be used in a route as a consumer, as this Java DSL example illustrates:

```
from("hl7NettyListener")
    .bean("patientLookupService");
```

48.3. HL7 MODEL USING JAVA.LANG.STRING OR BYTE[]

The HL7 MLLP codec uses plain String as its data format. Camel uses its Type Converter to convert to/from strings to the HAPI HL7 model objects, but you can use the plain String objects if you prefer, for instance if you wish to parse the data yourself.

You can also let both the Mina and Netty codecs use a plain **byte[]** as its data format by setting the **produceString** property to false. The Type Converter is also capable of converting the **byte[]** to/from HAPI HL7 model objects.

48.4. HL7V2 MODEL USING HAPI

The HL7v2 model uses Java objects from the HAPI library. Using this library, you can encode and decode from the EDI format (ER7) that is mostly used with HL7v2.

The sample below is a request to lookup a patient with the patient ID **0101701234**.

```
MSH|^~\&|MYSENDER|MYRECEIVER|MYAPPLICATION||200612211200||QRY^A19|1234|P|2.4
QRD|200612211200|R||GetPatient||1^RD|0101701234|DEM||
```

Using the HL7 model you can work with a **ca.uhn.hl7v2.model.Message** object, e.g. to retrieve a patient ID:

```
Message msg = exchange.getIn().getBody(Message.class);
QRD qrd = (QRD)msg.get("QRD");
String patientId = qrd.getWhoSubjectFilter(0).getIDNumber().getValue(); // 0101701234
```

This is powerful when combined with the HL7 listener, because you don't have to work with **byte[]**, **String** or any other simple object formats. You can just use the HAPI HL7v2 model objects. If you know the message type in advance, you can be more type-safe:

```
QRY_A19 msg = exchange.getIn().getBody(QRY_A19.class);
String patientId = msg.getQRD().getWhoSubjectFilter(0).getIDNumber().getValue();
```

48.5. HL7 DATAFORMAT

The **camel-hl7** JAR ships with a HL7 data format that can be used to marshal or unmarshal HL7 model objects.

The HL7 dataformat supports 1 options, which are listed below.

Name	Default	Java Type	Description
validate		Boolean	Whether to validate the HL7 message is by default true.

- **marshal** = from Message to byte stream (can be used when responding using the HL7 MLLP codec)
- **unmarshal** = from byte stream to Message (can be used when receiving streamed data from the HL7 MLLP)

To use the data format, simply instantiate an instance and invoke the marshal or unmarshal operation in the route builder:

```
DataFormat hl7 = new HL7DataFormat();

from("direct:hl7in")
  .marshal(hl7)
  .to("jms:queue:hl7out");
```

In the sample above, the HL7 is marshalled from a HAPI Message object to a byte stream and put on a JMS queue.

The next example is the opposite:

```
DataFormat hl7 = new HL7DataFormat();

from("jms:queue:hl7out")
  .unmarshal(hl7)
  .to("patientLookupService");
```

Here we unmarshal the byte stream into a HAPI Message object that is passed to our patient lookup service.

48.5.1. Segment separators

Unmarshalling does not automatically fix segment separators anymore by converting `\n` to `\r`. If you need this conversion, **org.apache.camel.component.hl7.HL7#convertLFToCR** provides a handy **Expression** for this purpose.

48.5.2. Charset

Both **marshal** and **unmarshal** evaluate the charset provided in the field **MSH-18**. If this field is empty, by default the charset contained in the corresponding Camel charset property/header is assumed. You can even change this default behavior by overriding the **guessCharsetName** method when inheriting

from the **HL7DataFormat** class.

There is a shorthand syntax in Camel for well-known data formats that are commonly used. Then you don't need to create an instance of the **HL7DataFormat** object:

```
from("direct:hl7in")
  .marshal().hl7()
  .to("jms:queue:hl7out");

from("jms:queue:hl7out")
  .unmarshal().hl7()
  .to("patientLookupService");
```

48.6. MESSAGE HEADERS

The unmarshal operation adds these fields from the MSH segment as headers on the Camel message:

Key	MSH field	Example
CamelHL7SendingApplication	MSH-3	MYSERVER
CamelHL7SendingFacility	MSH-4	MYSERVERAPP
CamelHL7ReceivingApplication	MSH-5	MYCLIENT
CamelHL7ReceivingFacility	MSH-6	MYCLIENTAPP
CamelHL7Timestamp	MSH-7	20071231235900
CamelHL7Security	MSH-8	null
CamelHL7MessageType	MSH-9-1	ADT
CamelHL7TriggerEvent	MSH-9-2	A01
CamelHL7MessageControl	MSH-10	1234
CamelHL7ProcessingId	MSH-11	P

Key	MSH field	Example
CamelHL7VersionId	MSH-12	2.4
CamelHL7Context		contains the that was used to parse the message
CamelHL7Charset	MSH-18	UNICODE UTF-8

All headers except **CamelHL7Context** are **String** types. If a header value is missing, its value is **null**.

48.7. DEPENDENCIES

To use HL7 in your Camel routes you'll need to add a dependency on **camel-hl7** listed above, which implements this data format.

The HAPI library is split into a [base library](#) and several structure libraries, one for each HL7v2 message version:

- [v2.1 structures library](#)
- [v2.2 structures library](#)
- [v2.3 structures library](#)
- [v2.3.1 structures library](#)
- [v2.4 structures library](#)
- [v2.5 structures library](#)
- [v2.5.1 structures library](#)
- [v2.6 structures library](#)

By default **camel-hl7** only references the HAPI [base library](#). Applications are responsible for including structure libraries themselves. For example, if an application works with HL7v2 message versions 2.4 and 2.5 then the following dependencies must be added:

```
<dependency>
  <groupId>ca.uhn.hapi</groupId>
  <artifactId>hapi-structures-v24</artifactId>
  <version>2.2</version>
  <!-- use the same version as your hapi-base version -->
</dependency>
<dependency>
  <groupId>ca.uhn.hapi</groupId>
  <artifactId>hapi-structures-v25</artifactId>
```

```
<version>2.2</version>
<!-- use the same version as your hapi-base version -->
</dependency>
```

Alternatively, an OSGi bundle containing the base library, all structures libraries and required dependencies (on the bundle classpath) can be downloaded from the [central Maven repository](#).

```
<dependency>
  <groupId>ca.uhn.hapi</groupId>
  <artifactId>hapi-osgi-base</artifactId>
  <version>2.2</version>
</dependency>
```

48.8. SPRING BOOT AUTO-CONFIGURATION

The component supports 4 options, which are listed below.

Name	Description	Default	Type
<code>camel.dataformat.hl7.enabled</code>	Whether to enable auto configuration of the hl7 data format. This is enabled by default.		Boolean
<code>camel.dataformat.hl7.validate</code>	Whether to validate the HL7 message ls by default true.	true	Boolean
<code>camel.language.hl7terser.enabled</code>	Whether to enable auto configuration of the hl7terser language. This is enabled by default.		Boolean
<code>camel.language.hl7terser.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean

CHAPTER 49. HTTP

Only producer is supported

The HTTP component provides HTTP based endpoints for calling external HTTP resources (as a client to call external servers using HTTP).

49.1. DEPENDENCIES

When using **http** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-http-starter</artifactId>
</dependency>
```

49.2. URI FORMAT

```
http:hostname[:port][/resourceUri][?options]
```

Will by default use port 80 for HTTP and 443 for HTTPS.

49.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

49.3.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).
- directly in the Java code.

49.3.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

49.4. COMPONENT OPTIONS

The HTTP component supports 40 options, which are listed below.

Name	Description	Default	Type
cookieStore (producer)	To use a custom <code>org.apache.http.client.CookieStore</code> . By default the <code>org.apache.http.impl.client.BasicCookieStore</code> is used which is an in-memory only cookie store. Notice if <code>bridgeEndpoint=true</code> then the cookie store is forced to be a noop cookie store as cookie shouldn't be stored as we are just bridging (eg acting as a proxy).		<code>CookieStore</code>
copyHeaders (producer)	If this option is true then IN exchange headers will be copied to OUT exchange headers according to copy strategy. Setting this to false, allows to only include the headers from the HTTP response (not propagating IN headers).	true	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow <code>CamelContext</code> and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
responsePayloadStreamingThreshold (producer)	This threshold in bytes controls whether the response payload should be stored in memory as a byte array or be streaming based. Set this to -1 to always use streaming mode.	8192	int

Name	Description	Default	Type
skipRequestHeaders (producer (advanced))	Whether to skip mapping all the Camel headers as HTTP request headers. If there are no data from Camel headers needed to be included in the HTTP request then this can avoid parsing overhead with many object allocations for the JVM garbage collector.	false	boolean
skipResponseHeaders (producer (advanced))	Whether to skip mapping all the HTTP response headers to Camel headers. If there are no data needed from HTTP headers then this can avoid parsing overhead with many object allocations for the JVM garbage collector.	false	boolean
followRedirects (producer (advanced))	Whether the HTTP request should follow redirects. By default the HTTP request does not follow redirects.	false	boolean
allowJavaSerializedObject (advanced)	Whether to allow java serialization when a request uses context-type=application/x-java-serialized-object. This is by default turned off. If you enable this then be aware that Java will deserialize the incoming data from the request to Java and that can be a potential security risk.	false	boolean
authCachingDisabled (advanced)	Disables authentication scheme caching.	false	boolean
automaticRetriesDisabled (advanced)	Disables automatic request recovery and re-execution.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
clientConnectionManager (advanced)	To use a custom and shared HttpClientConnectionManager to manage connections. If this has been configured then this is always used for all endpoints created by this component.		HttpClientConnectionManager
connectionsPerRoute (advanced)	The maximum number of connections per route.	20	int

Name	Description	Default	Type
connectionStateDisabled (advanced)	Disables connection state tracking.	false	boolean
connectionTimeToLive (advanced)	The time for connection to live, the time unit is millisecond, the default value is always keep alive.		long
contentCompressionDisabled (advanced)	Disables automatic content decompression.	false	boolean
cookieManagementDisabled (advanced)	Disables state (cookie) management.	false	boolean
defaultUserAgentDisabled (advanced)	Disables the default user agent set by this builder if none has been provided by the user.	false	boolean
httpBinding (advanced)	To use a custom HttpBinding to control the mapping between Camel message and HttpClient.		HttpBinding
httpClientConfigurer (advanced)	To use the custom HttpClientConfigurer to perform configuration of the HttpClient that will be used.		HttpClientConfigurer
httpConfiguration (advanced)	To use the shared HttpConfiguration as base configuration.		HttpConfiguration
httpContext (advanced)	To use a custom org.apache.http.protocol.HttpContext when executing requests.		HttpContext
maxTotalConnections (advanced)	The maximum number of connections.	200	int
redirectHandlingDisabled (advanced)	Disables automatic redirect handling.	false	boolean
headerFilterStrategy (filter)	To use a custom org.apache.camel.spi.HeaderFilterStrategy to filter header to and from Camel message.		HeaderFilterStrategy
proxyAuthDomain (proxy)	Proxy authentication domain to use.		String

Name	Description	Default	Type
proxyAuthHost (proxy)	Proxy authentication host.		String
proxyAuthMethod (proxy)	Proxy authentication method to use. Enum values: • Basic • Digest • NTLM		String
proxyAuthNtHost (proxy)	Proxy authentication domain (workstation name) to use with NTLM.		String
proxyAuthPassword (proxy)	Proxy authentication password.		String
proxyAuthPort (proxy)	Proxy authentication port.		Integer
proxyAuthUsername (proxy)	Proxy authentication username.		String
sslContextParameters (security)	To configure security using SSLContextParameters. Important: Only one instance of org.apache.camel.support.jsse.SSLContextParameters is supported per HttpComponent. If you need to use 2 or more different instances, you need to define a new HttpComponent per instance you need.		SSLContextParameters
useGlobalSslContextParameters (security)	Enable usage of global SSL context parameters.	false	boolean
x509HostnameVerifier (security)	To use a custom X509HostnameVerifier such as DefaultHostnameVerifier or NoopHostnameVerifier.		HostnameVerifier
connectionRequestTimeout (timeout)	The timeout in milliseconds used when requesting a connection from the connection manager. A timeout value of zero is interpreted as an infinite timeout. A timeout value of zero is interpreted as an infinite timeout. A negative value is interpreted as undefined (system default).	-1	int

Name	Description	Default	Type
connectTimeout (timeout)	Determines the timeout in milliseconds until a connection is established. A timeout value of zero is interpreted as an infinite timeout. A timeout value of zero is interpreted as an infinite timeout. A negative value is interpreted as undefined (system default).	-1	int
responseTimeout (timeout)	Determines the timeout until arrival of a response from the opposite endpoint. A timeout value of zero is interpreted as an infinite timeout. Please note that response timeout may be unsupported by HTTP transports with message multiplexing.	0	Timeout
soTimeout (timeout)	Determines the default socket timeout value for blocking I/O operations.	3 minute s	Timeout

49.5. ENDPOINT OPTIONS

The HTTP endpoint is configured using URI syntax:

```
http://httpUri
```

with the following path and query parameters:

49.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
httpUri (common)	Required The url of the HTTP endpoint to call.		URI

49.5.2. Query Parameters (54 parameters)

Name	Description	Default	Type
------	-------------	---------	------

Name	Description	Default	Type
disableStreamCache (common)	Determines whether or not the raw input stream is cached or not. The Camel consumer (camel-servlet, camel-jetty etc.) will by default cache the input stream to support reading it multiple times to ensure it Camel can retrieve all data from the stream. However you can set this option to true when you for example need to access the raw stream, such as streaming it directly to a file or other persistent store. DefaultHttpBinding will copy the request input stream into a stream cache and put it into message body if this option is false to support reading the stream multiple times. If you use Servlet to bridge/proxy an endpoint then consider enabling this option to improve performance, in case you do not need to read the message payload multiple times. The producer (camel-http) will by default cache the response body stream. If setting this option to true, then the producers will not cache the response body stream but use the response stream as-is (the stream can only be read once) as the message body.	false	boolean
headerFilterStrategy (common (advanced))	To use a custom HeaderFilterStrategy to filter header to and from Camel message.		HeaderFilterStrategy
bridgeEndpoint (producer)	If the option is true, HttpProducer will ignore the Exchange.HTTP_URI header, and use the endpoint's URI for request. You may also set the option <code>throwExceptionOnFailure</code> to be false to let the HttpProducer send all the fault response back.	false	boolean
connectionClose (producer)	Specifies whether a Connection Close header must be added to HTTP Request. By default <code>connectionClose</code> is false.	false	boolean

Name	Description	Default	Type
httpMethod (producer)	Configure the HTTP method to use. The HttpMethod header cannot override this option if set. Enum values: • GET • POST • PUT • DELETE • HEAD • OPTIONS • TRACE • PATCH		HttpMethods
skipRequestHeaders (producer)	Whether to skip mapping all the Camel headers as HTTP request headers. If there are no data from Camel headers needed to be included in the HTTP request then this can avoid parsing overhead with many object allocations for the JVM garbage collector.	false	boolean
skipResponseHeaders (producer)	Whether to skip mapping all the HTTP response headers to Camel headers. If there are no data needed from HTTP headers then this can avoid parsing overhead with many object allocations for the JVM garbage collector.	false	boolean
throwExceptionOnFailure (producer)	Option to disable throwing the <code>HttpOperationFailedException</code> in case of failed responses from the remote server. This allows you to get all responses regardless of the HTTP status code.	true	boolean
clearExpiredCookies (producer (advanced))	Whether to clear expired cookies before sending the HTTP request. This ensures the cookies store does not keep growing by adding new cookies which is never removed when they are expired. If the component has disabled cookie management then this option is disabled too.	true	boolean
cookieHandler (producer (advanced))	Configure a cookie handler to maintain a HTTP session.		CookieHandler

Name	Description	Default	Type
cookieStore (producer (advanced))	To use a custom CookieStore. By default the BasicCookieStore is used which is an in-memory only cookie store. Notice if bridgeEndpoint=true then the cookie store is forced to be a noop cookie store as cookie shouldn't be stored as we are just bridging (eg acting as a proxy). If a cookieHandler is set then the cookie store is also forced to be a noop cookie store as cookie handling is then performed by the cookieHandler.		CookieStore
copyHeaders (producer (advanced))	If this option is true then IN exchange headers will be copied to OUT exchange headers according to copy strategy. Setting this to false, allows to only include the headers from the HTTP response (not propagating IN headers).	true	boolean
customHostHeader (producer (advanced))	To use custom host header for producer. When not set in query will be ignored. When set will override host header derived from url.		String
deleteWithBody (producer (advanced))	Whether the HTTP DELETE should include the message body or not. By default HTTP DELETE do not include any HTTP body. However in some rare cases users may need to be able to include the message body.	false	boolean
followRedirects (producer (advanced))	Whether the HTTP request should follow redirects. By default the HTTP request does not follow redirects.	false	boolean
getWithBody (producer (advanced))	Whether the HTTP GET should include the message body or not. By default HTTP GET do not include any HTTP body. However in some rare cases users may need to be able to include the message body.	false	boolean
ignoreResponseBody (producer (advanced))	If this option is true, The http producer won't read response body and cache the input stream.	false	boolean

Name	Description	Default	Type
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
okStatusCodeRange (producer (advanced))	The status codes which are considered a success response. The values are inclusive. Multiple ranges can be defined, separated by comma, e.g. 200-204,209,301-304. Each range must be a single number or from-to with the dash included.	200-299	String
preserveHostHeader (producer (advanced))	If the option is true, HttpProducer will set the Host header to the value contained in the current exchange Host header, useful in reverse proxy applications where you want the Host header received by the downstream server to reflect the URL called by the upstream client, this allows applications which use the Host header to generate accurate URL's for a proxied service.	false	boolean
userAgent (producer (advanced))	To set a custom HTTP User-Agent request header.		String
clientBuilder (advanced)	Provide access to the http client request parameters used on new RequestConfig instances used by producers or consumers of this endpoint.		HttpClientBuilder
clientConnectionManager (advanced)	To use a custom HttpClientConnectionManager to manage connections.		HttpClientConnectionManager
connectionsPerRoute (advanced)	The maximum number of connections per route.	20	int
httpClient (advanced)	Sets a custom HttpClient to be used by the producer.		HttpClient
httpClientConfigurer (advanced)	Register a custom configuration strategy for new HttpClient instances created by producers or consumers such as to configure authentication mechanisms etc.		HttpClientConfigurer

Name	Description	Default	Type
httpClientOptions (advanced)	To configure the HttpClient using the key/values from the Map.		Map
httpConnectionOptions (advanced)	To configure the connection and the socket using the key/values from the Map.		Map
httpContext (advanced)	To use a custom HttpContext instance.		HttpContext
maxTotalConnections (advanced)	The maximum number of connections.	200	int
useSystemProperties (advanced)	To use System Properties as fallback for configuration.	false	boolean
proxyAuthDomain (proxy)	Proxy authentication domain to use with NTLM.		String
proxyAuthHost (proxy)	Proxy authentication host.		String
proxyAuthMethod (proxy)	Proxy authentication method to use. Enum values: • Basic • Digest • NTLM		String
proxyAuthNtHost (proxy)	Proxy authentication domain (workstation name) to use with NTLM.		String
proxyAuthPassword (proxy)	Proxy authentication password.		String
proxyAuthPort (proxy)	Proxy authentication port.		int
proxyAuthScheme (proxy)	Proxy authentication scheme to use. Enum values: • http • https		String

Name	Description	Default	Type
proxyAuthUsername (proxy)	Proxy authentication username.		String
proxyHost (proxy)	Proxy hostname to use.		String
proxyPort (proxy)	Proxy port to use.		int
authDomain (security)	Authentication domain to use with NTLM.		String
authenticationPreemptive (security)	If this option is true, camel-http sends preemptive basic authentication to the server.	false	boolean
authHost (security)	Authentication host to use with NTLM.		String
authMethod (security)	Authentication methods allowed to use as a comma separated list of values Basic, Digest or NTLM.		String
authMethodPriority (security)	Which authentication method to prioritize to use, either as Basic, Digest or NTLM. Enum values: • Basic • Digest • NTLM		String
authPassword (security)	Authentication password.		String
authUsername (security)	Authentication username.		String
oauth2ClientId (security)	OAuth2 client id.		String
oauth2ClientSecret (security)	OAuth2 client secret.		String
oauth2Scope (security)	OAuth2 scope.		String

Name	Description	Default	Type
oauth2TokenEndpoint (security)	OAuth2 Token endpoint.		String
sslContextParameters (security)	To configure security using SSLContextParameters. Important: Only one instance of org.apache.camel.util.jsse.SSLContextParameters is supported per HttpComponent. If you need to use 2 or more different instances, you need to define a new HttpComponent per instance you need.		SSLContextParameters
x509HostnameVerifier (security)	To use a custom X509HostnameVerifier such as DefaultHostnameVerifier or NoopHostnameVerifier.		HostnameVerifier

49.6. MESSAGE HEADERS

Name	Description	Default	Type
Content-Encoding (producer) Constant: CONTENT_ENCODING	The HTTP content encoding. Is set on both the IN and OUT message to provide a content encoding, such as gzip.		String
CamelHttpResponseCode (producer) Constant: HTTP_RESPONSE_CODE	The HTTP response code from the external server. Is 200 for OK.		int
CamelHttpResponseText (producer) Constant: HTTP_RESPONSE_TEXT	The HTTP response text from the external server.		String
CamelHttpQuery (producer) Constant: HTTP_QUERY	URI parameters. Will override existing URI parameters set directly on the endpoint.		String

Name	Description	Default	Type
CamelHttpProtocolVersion (producer) Constant: HTTP_PROTOCOL_VERSION	The version of the http protocol used.		String
Host (producer) Constant: HTTP_HEADER_HOST	The target host.		String
CamelRestHttpUri (producer) Constant: REST_HTTP_URI	The rest http URI.		String
CamelHttpUri (producer) Constant: HTTP_URI	URI to call. Will override existing URI set directly on the endpoint. This uri is the uri of the http server to call. Its not the same as the Camel endpoint uri, where you can configure endpoint options such as security etc. This header does not support that, its only the uri of the http server.		String
CamelHttpPath (producer) Constant: HTTP_PATH	Request URI's path, the header will be used to build the request URI with the HTTP_URI.		String
CamelRestHttpQuery (producer) Constant: REST_HTTP_QUERY	The rest http query.		String
CamelHttpRawQuery (producer) Constant: HTTP_RAW_QUERY	The http raw query.		String

Name	Description	Default	Type
CamelHttpMethod (producer) Constant: HTTP_METHOD	The http method to use. Enum values: • GET • PATCH • POST • PUT • DELETE • HEAD • OPTIONS • TRACE		HttpMethods
CamelHttpCharacterEncoding (producer) Constant: HTTP_CHARACTER_ENCODING	The character encoding.		String
Content-Type (producer) Constant: CONTENT_TYPE	The HTTP content type. Is set on both the IN and OUT message to provide a content type, such as text/html.		String

NOTE

Avoid creating your own HTTP server instances in a Camel Spring Boot application by using either of the **cxfrt-transport-jetty**, **cxfrt-transport-netty-server**, **cxfrt-transport-underflow** libraries. It is recommended to use the Spring Boot embedded HTTP server stack which is created when you use the **spring-boot-starter-web**, **cxfrt-spring-boot-starter-jaxrs**, or **cxfrt-spring-boot-starter-jaxws** dependencies.

49.7. MESSAGE BODY

Camel will store the HTTP response from the external server on the OUT body. All headers from the IN message will be copied to the OUT message, so headers are preserved during routing. Additionally Camel will add the HTTP response headers as well to the OUT message headers.

49.8. USING SYSTEM PROPERTIES

When setting `useSystemProperties` to `true`, the HTTP Client will look for the following System Properties and it will use it:

- `ssl.TrustManagerFactory.algorithm`
- [javax.net.ssl.trustStoreType](#)
- [javax.net.ssl.trustStore](#)
- [javax.net.ssl.trustStoreProvider](#)
- [javax.net.ssl.trustStorePassword](#)
- `java.home`
- `ssl.KeyManagerFactory.algorithm`
- [javax.net.ssl.keyStoreType](#)
- [javax.net.ssl.keyStore](#)
- [javax.net.ssl.keyStoreProvider](#)
- [javax.net.ssl.keyStorePassword](#)
- `http.proxyHost`
- `http.proxyPort`
- `http.nonProxyHosts`
- `http.keepAlive`
- `http.maxConnections`

49.9. RESPONSE CODE

Camel will handle according to the HTTP response code:

- Response code is in the range 100..299, Camel regards it as a success response.
- Response code is in the range 300..399, Camel regards it as a redirection response and will throw a **HttpOperationFailedException** with the information.
- Response code is 400+, Camel regards it as an external server failure and will throw a **HttpOperationFailedException** with the information.

throwExceptionOnFailure The option, **throwExceptionOnFailure**, can be set to **false** to prevent the **HttpOperationFailedException** from being thrown for failed response codes. This allows you to get any response from the remote server.

There is a sample below demonstrating this.

49.10. EXCEPTIONS

HttpOperationFailedException exception contains the following information:

- The HTTP status code
- The HTTP status line (text of the status code)

- Redirect location, if server returned a redirect
- Response body as a **java.lang.String**, if server provided a body as response

49.11. WHICH HTTP METHOD WILL BE USED

The following algorithm is used to determine what HTTP method should be used:

1. Use method provided as endpoint configuration (**httpMethod**).
2. Use method provided in header (**Exchange.HTTP_METHOD**).
3. **GET** if query string is provided in header.
4. **GET** if endpoint is configured with a query string.
5. **POST** if there is data to send (body is not **null**).
6. **GET** otherwise.

49.12. HOW TO GET ACCESS TO HTTPServletRequest AND HttpServletResponse

You can get access to these two using the Camel type converter system using

```
HttpServletRequest request = exchange.getIn().getBody(HttpServletRequest.class);
HttpServletResponse response = exchange.getIn().getBody(HttpServletResponse.class);
```

NOTE

You can get the request and response not just from the processor after the camel-jetty or camel-cxf endpoint.

49.13. CONFIGURING URI TO CALL

You can set the HTTP producer's URI directly from the endpoint URI. In the route below, Camel will call out to the external server, **oldhost**, using HTTP.

```
from("direct:start")
    .to("http://oldhost");
```

And the equivalent Spring sample:

```
<camelContext xmlns="http://activemq.apache.org/camel/schema/spring">
  <route>
    <from uri="direct:start"/>
    <to uri="http://oldhost"/>
  </route>
</camelContext>
```

You can override the HTTP endpoint URI by adding a header with the key, **Exchange.HTTP_URI**, on the message.

```
from("direct:start")
    .setHeader(Exchange.HTTP_URI, constant("http://newhost"))
    .to("http://oldhost");
```

In the sample above Camel will call the <http://newhost/> despite the endpoint is configured with <http://oldhost/>.

If the http endpoint is working in bridge mode, it will ignore the message header of **Exchange.HTTP_URI**.

49.14. CONFIGURING URI PARAMETERS

The **http** producer supports URI parameters to be sent to the HTTP server. The URI parameters can either be set directly on the endpoint URI or as a header with the key **Exchange.HTTP_QUERY** on the message.

```
from("direct:start")
  .to("http://oldhost?order=123&detail=short");
```

Or options provided in a header:

```
from("direct:start")
  .setHeader(Exchange.HTTP_QUERY, constant("order=123&detail=short"))
  .to("http://oldhost");
```

49.15. HOW TO SET THE HTTP METHOD (GET/PATCH/POST/PUT/DELETE/HEAD/OPTIONS/TRACE) TO THE HTTP PRODUCER

The HTTP component provides a way to set the HTTP request method by setting the message header. Here is an example:

```
from("direct:start")
  .setHeader(Exchange.HTTP_METHOD,
    constant(org.apache.camel.component.http.HttpMethods.POST))
  .to("http://www.google.com")
  .to("mock:results");
```

The method can be written a bit shorter using the string constants:

```
.setHeader("CamelHttpMethod", constant("POST"))
```

And the equivalent Spring sample:

```
<camelContext xmlns="http://activemq.apache.org/camel/schema/spring">
  <route>
    <from uri="direct:start"/>
    <setHeader name="CamelHttpMethod">
      <constant>POST</constant>
    </setHeader>
    <to uri="http://www.google.com"/>
    <to uri="mock:results"/>
  </route>
</camelContext>
```

49.16. USING CLIENT TIMEOUT - SO_TIMEOUT

See the [HttpSOTimeoutTest](#) unit test.

49.17. CONFIGURING A PROXY

The HTTP component provides a way to configure a proxy.

```
from("direct:start")
  .to("http://oldhost?proxyAuthHost=www.myproxy.com&proxyAuthPort=80");
```

There is also support for proxy authentication via the **proxyAuthUsername** and **proxyAuthPassword** options.

49.17.1. Using proxy settings outside of URI

To avoid System properties conflicts, you can set proxy configuration only from the CamelContext or URI.

Java DSL :

```
context.getGlobalOptions().put("http.proxyHost", "172.168.18.9");
context.getGlobalOptions().put("http.proxyPort", "8080");
```

Spring XML

```
<camelContext>
  <properties>
    <property key="http.proxyHost" value="172.168.18.9"/>
    <property key="http.proxyPort" value="8080"/>
  </properties>
</camelContext>
```

Camel will first set the settings from Java System or CamelContext Properties and then the endpoint proxy options if provided.

So you can override the system properties with the endpoint options.

There is also a **http.proxyScheme** property you can set to explicit configure the scheme to use.

49.18. CONFIGURING CHARSET

If you are using **POST** to send data you can configure the **charset** using the **Exchange** property:

```
exchange.setProperty(Exchange.CHARSET_NAME, "ISO-8859-1");
```

49.18.1. Sample with scheduled poll

This sample polls the Google homepage every 10 seconds and write the page to the file **message.html**:

```
from("timer://foo?fixedRate=true&delay=0&period=10000")
  .to("http://www.google.com")
  .setHeader(FileComponent.HEADER_FILE_NAME, "message.html")
  .to("file:target/google");
```

49.18.2. URI Parameters from the endpoint URI

In this sample we have the complete URI endpoint that is just what you would have typed in a web browser. Multiple URI parameters can of course be set using the **&** character as separator, just as you would in the web browser. Camel does no tricks here.

```
// we query for Camel at the Google page
template.sendBody("http://www.google.com/search?q=Camel", null);
```

49.18.3. URI Parameters from the Message

```
Map headers = new HashMap();
headers.put(Exchange.HTTP_QUERY, "q=Camel&lr=lang_en");
// we query for Camel and English language at Google
template.sendBody("http://www.google.com/search", null, headers);
```

In the header value above notice that it should **not** be prefixed with **?** and you can separate parameters as usual with the **&** char.

49.18.4. Getting the Response Code

You can get the HTTP response code from the HTTP component by getting the value from the Out message header with **Exchange.HTTP_RESPONSE_CODE**.

```
Exchange exchange = template.send("http://www.google.com/search", new Processor() {
    public void process(Exchange exchange) throws Exception {
        exchange.getIn().setHeader(Exchange.HTTP_QUERY, constant("hl=en&q=activemq"));
    }
});
Message out = exchange.getOut();
int responseCode = out.getHeader(Exchange.HTTP_RESPONSE_CODE, Integer.class);
```

49.19. DISABLING COOKIES

To disable cookies you can set the HTTP Client to ignore cookies by adding the following URI option:

```
httpClient.cookieSpec=ignore
```

49.20. BASIC AUTH WITH THE STREAMING MESSAGE BODY

In order to avoid the **NonRepeatableRequestException**, you need to do the Preemptive Basic Authentication by adding the option:

authenticationPreemptive=true

49.21. ADVANCED USAGE

If you need more control over the HTTP producer you should use the **HttpComponent** where you can set various classes to give you custom behavior.

49.21.1. Setting up SSL for HTTP Client

Using the JSSE Configuration Utility

The HTTP component supports SSL/TLS configuration through the [Camel JSSE Configuration Utility](#). This utility greatly decreases the amount of component specific code you need to write and is configurable at the endpoint and component levels.

The following examples demonstrate how to use the utility with the HTTP component.

Programmatic configuration of the component

```
KeyStoreParameters ksp = new KeyStoreParameters();
ksp.setResource("file:/users/home/server/keystore.jks");
ksp.setPassword("keystorePassword");

KeyManagersParameters kmp = new KeyManagersParameters();
kmp.setKeyStore(ksp);
kmp.setKeyPassword("keyPassword");

SSLContextParameters scp = new SSLContextParameters();
scp.setKeyManagers(kmp);

HttpComponent httpComponent = getContext().getComponent("https", HttpComponent.class);
httpComponent.setSslContextParameters(scp);
```

Spring DSL based configuration of endpoint

```
<camel:sslContextParameters
  id="sslContextParameters">
  <camel:keyManagers
    keyPassword="keyPassword">
    <camel:keyStore
      resource="file:/users/home/server/keystore.jks"
      password="keystorePassword"/>
    </camel:keyManagers>
  </camel:sslContextParameters>

  <to uri="https://127.0.0.1/mail/?sslContextParameters=#sslContextParameters"/>
```

Configuring Apache HTTP Client Directly

Basically camel-http component is built on the top of [Apache HttpClient](#). Please refer to [SSL/TLS customization](#) for details or have a look into the

org.apache.camel.component.http.HttpsServerTestSupport unit test base class.

You can also implement a custom **org.apache.camel.component.http.HttpClientConfigurer** to do some configuration on the http client if you need full control of it.

However if you *just* want to specify the keystore and truststore you can do this with Apache HTTP **HttpClientConfigurer**, for example:

```
KeyStore keystore = ...;
KeyStore truststore = ...;

SchemeRegistry registry = new SchemeRegistry();
registry.register(new Scheme("https", 443, new SSLSocketFactory(keystore, "mypassword",
truststore)));
```

And then you need to create a class that implements **HttpClientConfigurer**, and registers https protocol providing a keystore or truststore per example above. Then, from your camel route builder class you can hook it up like so:

```
HttpComponent httpComponent = getContext().getComponent("http", HttpComponent.class);
httpComponent.setHttpClientConfigurer(new MyHttpClientConfigurer());
```

If you are doing this using the Spring DSL, you can specify your **HttpClientConfigurer** using the URI. For example:

```
<bean id="myHttpClientConfigurer"
class="my.https.HttpClientConfigurer">
</bean>

<to uri="https://myhostname.com:443/myURL?httpClientConfigurer=myHttpClientConfigurer"/>
```

As long as you implement the HttpClientConfigurer and configure your keystore and truststore as described above, it will work fine.

Using HTTPS to authenticate gotchas

An end user reported that he had problem with authenticating with HTTPS. The problem was eventually resolved by providing a custom configured **org.apache.http.protocol.HttpContext**:

1. Create a (Spring) factory for HttpContexts.

```
public class HttpContextFactory {

    private String httpHost = "localhost";
    private String httpPort = "9001";

    private BasicHttpContext httpContext = new BasicHttpContext();
    private BasicAuthCache authCache = new BasicAuthCache();
    private BasicScheme basicAuth = new BasicScheme();

    public HttpContext getObject() {
        authCache.put(new HttpHost(httpHost, httpPort), basicAuth);

        httpContext.setAttribute(ClientContext.AUTH_CACHE, authCache);

        return httpContext;
    }

    // getter and setter
}
```

2. Declare an HttpContext in the Spring application context file.

```
<bean id="myHttpContext" factory-bean="httpContextFactory" factory-method="getObject"/>
```

3. Reference the context in the http URL:

```
<to uri="https://myhostname.com:443/myURL?httpContext=myHttpContext"/>
```

Using different SSLContextParameters

The [HTTP](#) component only support one instance of **org.apache.camel.support.jsse.SSLContextParameters** per component. If you need to use 2 or more different instances, then you need to setup multiple [HTTP](#) components as shown below. Where we have 2 components, each using their own instance of **sslContextParameters** property.

```
<bean id="http-foo" class="org.apache.camel.component.http.HttpComponent">
  <property name="sslContextParameters" ref="sslContextParams1"/>
  <property name="x509HostnameVerifier" ref="hostnameVerifier"/>
</bean>

<bean id="http-bar" class="org.apache.camel.component.http.HttpComponent">
  <property name="sslContextParameters" ref="sslContextParams2"/>
  <property name="x509HostnameVerifier" ref="hostnameVerifier"/>
</bean>
```

For more information about how to configure SSL see [http-ssl](#) example.

49.22. SPRING BOOT AUTO-CONFIGURATION

The component supports 41 options, which are listed below.

Name	Description	Default	Type
camel.component.http.allow-java-serialized-object	Whether to allow java serialization when a request uses context-type=application/x-java-serialized-object. This is by default turned off. If you enable this then be aware that Java will deserialize the incoming data from the request to Java and that can be a potential security risk.	false	Boolean
camel.component.http.auth-caching-disabled	Disables authentication scheme caching.	false	Boolean
camel.component.http.automatic-retries-disabled	Disables automatic request recovery and re-execution.	false	Boolean
camel.component.http.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
<code>camel.component.http.client-connection-manager</code>	To use a custom and shared <code>HttpClientConnectionManager</code> to manage connections. If this has been configured then this is always used for all endpoints created by this component. The option is a <code>org.apache.http.conn.HttpClientConnectionManager</code> type.		<code>HttpClientConnectionManager</code>
<code>camel.component.http.connect-timeout</code>	Determines the timeout in milliseconds until a connection is established. A timeout value of zero is interpreted as an infinite timeout. A timeout value of zero is interpreted as an infinite timeout. A negative value is interpreted as undefined (system default).	-1	Integer
<code>camel.component.http.connection-request-timeout</code>	The timeout in milliseconds used when requesting a connection from the connection manager. A timeout value of zero is interpreted as an infinite timeout. A timeout value of zero is interpreted as an infinite timeout. A negative value is interpreted as undefined (system default).	-1	Integer
<code>camel.component.http.connection-state-disabled</code>	Disables connection state tracking.	false	Boolean
<code>camel.component.http.connection-time-to-live</code>	The time for connection to live, the time unit is millisecond, the default value is always keep alive.		Long
<code>camel.component.http.connections-per-route</code>	The maximum number of connections per route.	20	Integer
<code>camel.component.http.content-compression-disabled</code>	Disables automatic content decompression.	false	Boolean
<code>camel.component.http.cookie-management-disabled</code>	Disables state (cookie) management.	false	Boolean

Name	Description	Default	Type
camel.component.http.cookie-store	To use a custom <code>org.apache.http.client.CookieStore</code> . By default the <code>org.apache.http.impl.client.BasicCookieStore</code> is used which is an in-memory only cookie store. Notice if <code>bridgeEndpoint=true</code> then the cookie store is forced to be a noop cookie store as cookie shouldn't be stored as we are just bridging (eg acting as a proxy). The option is a <code>org.apache.http.client.CookieStore</code> type.		<code>CookieStore</code>
camel.component.http.copy-headers	If this option is true then IN exchange headers will be copied to OUT exchange headers according to copy strategy. Setting this to false, allows to only include the headers from the HTTP response (not propagating IN headers).	true	Boolean
camel.component.http.default-user-agent-disabled	Disables the default user agent set by this builder if none has been provided by the user.	false	Boolean
camel.component.http.enabled	Whether to enable auto configuration of the http component. This is enabled by default.		Boolean
camel.component.http.follow-redirects	Whether to the HTTP request should follow redirects. By default the HTTP request does not follow redirects.	false	Boolean
camel.component.http.header-filter-strategy	To use a custom <code>org.apache.camel.spi.HeaderFilterStrategy</code> to filter header to and from Camel message. The option is a <code>org.apache.camel.spi.HeaderFilterStrategy</code> type.		<code>HeaderFilterStrategy</code>
camel.component.http.http-binding	To use a custom <code>HttpBinding</code> to control the mapping between Camel message and <code>HttpClient</code> . The option is a <code>org.apache.camel.http.common.HttpBinding</code> type.		<code>HttpBinding</code>
camel.component.http.http-client-configurer	To use the custom <code>HttpClientConfigurer</code> to perform configuration of the <code>HttpClient</code> that will be used. The option is a <code>org.apache.camel.component.http.HttpClientConfigurer</code> type.		<code>HttpClientConfigurer</code>
camel.component.http.http-configuration	To use the shared <code>HttpConfiguration</code> as base configuration. The option is a <code>org.apache.camel.http.common.HttpConfiguration</code> type.		<code>HttpConfiguration</code>

Name	Description	Default	Type
camel.component.http.http-context	To use a custom <code>org.apache.http.protocol.HttpContext</code> when executing requests. The option is a <code>org.apache.http.protocol.HttpContext</code> type.		HttpContext
camel.component.http.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.http.max-total-connections	The maximum number of connections.	200	Integer
camel.component.http.proxy-auth-domain	Proxy authentication domain to use.		String
camel.component.http.proxy-auth-host	Proxy authentication host.		String
camel.component.http.proxy-auth-method	Proxy authentication method to use.		String
camel.component.http.proxy-auth-nt-host	Proxy authentication domain (workstation name) to use with NTLM.		String
camel.component.http.proxy-auth-password	Proxy authentication password.		String
camel.component.http.proxy-auth-port	Proxy authentication port.		Integer

Name	Description	Default	Type
<code>camel.component.http.proxy-auth-scheme</code>	Proxy authentication protocol scheme.		String
<code>camel.component.http.proxy-auth-username</code>	Proxy authentication username.		String
<code>camel.component.http.redirect-handling-disabled</code>	Disables automatic redirect handling.	false	Boolean
<code>camel.component.http.response-payload-streaming-threshold</code>	This threshold in bytes controls whether the response payload should be stored in memory as a byte array or be streaming based. Set this to -1 to always use streaming mode.	8192	Integer
<code>camel.component.http.response-timeout</code>	Determines the timeout until arrival of a response from the opposite endpoint. A timeout value of zero is interpreted as an infinite timeout. Please note that response timeout may be unsupported by HTTP transports with message multiplexing. The option is a <code>org.apache.hc.core5.util.Timeout</code> type.		Timeout
<code>camel.component.http.skip-request-headers</code>	Whether to skip mapping all the Camel headers as HTTP request headers. If there are no data from Camel headers needed to be included in the HTTP request then this can avoid parsing overhead with many object allocations for the JVM garbage collector.	false	Boolean
<code>camel.component.http.skip-response-headers</code>	Whether to skip mapping all the HTTP response headers to Camel headers. If there are no data needed from HTTP headers then this can avoid parsing overhead with many object allocations for the JVM garbage collector.	false	Boolean
<code>camel.component.http.so-timeout</code>	Determines the default socket timeout value for blocking I/O operations. The option is a <code>org.apache.hc.core5.util.Timeout</code> type.		Timeout

Name	Description	Default	Type
camel.component.http.ssl-context-parameters	To configure security using SSLContextParameters. Important: Only one instance of org.apache.camel.support.jsse.SSLContextParameters is supported per HttpComponent. If you need to use 2 or more different instances, you need to define a new HttpComponent per instance you need. The option is a org.apache.camel.support.jsse.SSLContextParameters type.		SSLContextParameters
camel.component.http.use-global-ssl-context-parameters	Enable usage of global SSL context parameters.	false	Boolean
camel.component.http.x509-hostname-verifier	To use a custom X509HostnameVerifier such as DefaultHostnameVerifier or NoopHostnameVerifier. The option is a javax.net.ssl.HostnameVerifier type.		HostnameVerifier

CHAPTER 50. HASHICORP VAULT

Since Camel 3.18

Only producer is supported

The hashicorp-vault component that integrates [Hashicorp Vault](#).

50.1. DEPENDENCIES

When using **hashicorp-vault** Red Hat build of Camel Spring Boot, add the following Maven dependency to your **pom.xml** to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-hashicorp-vault-starter</artifactId>
</dependency>
```

50.2. CONFIGURING OPTIONS

Camel components are configured on two levels:

- Component level
- Endpoint level

50.2.1. Component Level Options

The **component level** is the highest level. The configurations you define at this level are inherited by all the endpoints. For example, a component can have security settings, credentials for authentication, urls for network connection, and so on.

Since components typically have pre-configured defaults for the most common cases, you may need to only configure a few component options, or maybe none at all.

You can configure components with

- [Component DSL](#)
- in a configuration file (**application.properties** or **yaml**),
- directly with Java code.

50.2.2. Endpoint Level Options

At the **Endpoint level** you have many options, which you can use to configure what you want the endpoint to do. The options are categorized according to whether the endpoint is used as a consumer (*from*) or as a producer (*to*) or used for both.

You can configure endpoints directly in the endpoint URI as **path** and **query** parameters. You can also use [Endpoint DSL](#) and [DataFormat DSL](#) as *type safe* ways of configuring endpoints and data formats in Java.

When configuring options, use [Property Placeholders](#) for urls, port numbers, sensitive information, and other settings.

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

50.3. COMPONENT OPTIONS

The Hashicorp Vault component supports 2 options, which are listed below.

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

50.4. ENDPOINT OPTIONS

The Hashicorp Vault endpoint is configured using URI syntax:

```
hashicorp-vault:secretsEngine
```

With the following *path* and *query* parameters:

50.4.1. Path Parameters (1 parameters)

Name	Description	Default	Type
------	-------------	---------	------

Name	Description	Default	Type
secretsEngine (producer)	Vault Name to be used.		String

50.4.2. Query Parameters (8 parameters)

Name	Description	Default	Type
host (producer)	Hashicorp Vault instance host to be used.		String
operation (producer)	Operation to be performed. Enum values: • createSecret • getSecret • deleteSecret • listSecrets		Hashicorp Vault Operation
port (producer)	Hashicorp Vault instance port to be used.	8200	String
scheme (producer)	Hashicorp Vault instance scheme to be used.	https	String
secretPath (producer)	Hashicorp Vault instance secret Path to be used.		String
vaultTemplate (producer)	Autowired Instance of Vault template.		Vault Template

Name	Description	Default	Type
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
token (security)	Token to be used.		String

50.5. MESSAGE HEADERS

The Hashicorp Vault component supports 3 message header(s), which is/are listed below:

Name	Description	Default	Type
CamelHashicorpVaultProducerOperation (producer) Constant: OPERATION	Overrides the desired operation to be used in the producer.		String
CamelHashicorpVaultSecretPath (producer) Constant: SECRET_PATH	Set the desired secret path as header.		String
CamelHashicorpVaultSecretVersion (producer) Constant: SECRET_VERSION	Set the desired secret version as header.		String

50.6. EXAMPLES

50.6.1. Using Hashicorp Vault Property Function

To use this function, you'll need to provide credentials for Hashicorp vault as environment variables:

```
export $CAMEL_VAULT_HASHICORP_TOKEN=token
export $CAMEL_VAULT_HASHICORP_HOST=host
export $CAMEL_VAULT_HASHICORP_PORT=port
export $CAMEL_VAULT_HASHICORP_SCHEME=http/https
```

You can also configure the credentials in the **application.properties** file such as:

```
camel.vault.hashicorp.token = token
camel.vault.hashicorp.host = host
camel.vault.hashicorp.port = port
camel.vault.hashicorp.scheme = scheme
```

NOTE

camel.vault.hashicorp configuration only applies to the Hashicorp Vault properties function (E.g when resolving properties). When using the **operation** option to create, get, list secrets etc., you should provide the **host**, **port**, **scheme** (if required) & **token** options.

At this point, you'll be able to reference a property in the following way:

```
<camelContext>
  <route>
    <from uri="direct:start"/>
    <to uri="{{hashicorp:secret:route}}"/>
  </route>
</camelContext>
```

Where **route** is the name of the secret stored in the Hashicorp Vault instance, in the 'secret' engine.

You must specify a default value in case the secret is not present on Hashicorp Vault instance:

```
<camelContext>
  <route>
    <from uri="direct:start"/>
    <to uri="{{hashicorp:secret:route:default}}"/>
  </route>
</camelContext>
```

In this case, if the secret doesn't exist in the 'secret' engine, the property will fall back to "default" as value.

Also, you are able to get a particular field of the secret, if you have, for example, a secret named database of this form:

```
{
  "username": "admin",
  "password": "password123",
  "engine": "postgres",
  "host": "127.0.0.1",
```

```
"port": "3128",
"dbname": "db"
}
```

You can have a single secret value in your route, in the 'secret' engine, for example:

```
<camelContext>
  <route>
    <from uri="direct:start"/>
    <log message="Username is {{hashicorp:secret:database/username}}"/>
  </route>
</camelContext>
```

Or re-use the property as part of an endpoint.

Specify a default value in case the particular field of secret is not present on Hashicorp Vault instance, in the 'secret' engine:

```
<camelContext>
  <route>
    <from uri="direct:start"/>
    <log message="Username is {{hashicorp:secret:database/username:admin}}"/>
  </route>
</camelContext>
```

In this case, if the secret doesn't exist or the secret exists (in the 'secret' engine) but the username field is not part of the secret, the property will fall back to "admin" as value.

There is also the syntax to get a particular version of the secret for both the approach, with field/default value specified or only with secret:

```
<camelContext>
  <route>
    <from uri="direct:start"/>
    <to uri="{{hashicorp:secret:route@2}}"/>
  </route>
</camelContext>
```

This approach returns the RAW route secret with version '2', in the 'secret' engine.

```
<camelContext>
  <route>
    <from uri="direct:start"/>
    <to uri="{{hashicorp:route:default@2}}"/>
  </route>
</camelContext>
```

This approach will return the route secret value with version '2' or default value in case the secret doesn't exist or the version doesn't exist (in the 'secret' engine).

```
<camelContext>
  <route>
    <from uri="direct:start"/>
```

```

    <log message="Username is {{hashicorp:secret:database/username:admin@2}}"/>
  </route>
</camelContext>

```

This approach will return the username field of the database secret with version '2' or admin in case the secret doesn't exist or the version doesn't exist (in the 'secret' engine).

The only requirement is adding the camel-hashicorp-vault jar to your Camel application.

50.7. SPRING BOOT AUTO-CONFIGURATION

When using hashicorp-vault with Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

The component supports 3 options, which are listed below.

Name	Description	Default	Type
camel.component.hashicorp-vault.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.hashicorp-vault.enabled	Whether to enable auto configuration of the hashicorp-vault component. This is enabled by default.		Boolean
camel.component.hashicorp-vault.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

CHAPTER 51. INFINISPAN

Both producer and consumer are supported

This component allows you to interact with [Infinispan](#) distributed data grid / cache using the Hot Rod protocol. Infinispan is an extremely scalable, highly available key/value data store and data grid platform written in Java.

51.1. DEPENDENCIES

When using **infinispan** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-infinispan-starter</artifactId>
</dependency>
```

51.2. URI FORMAT

```
infinispan://cacheName?[options]
```

The producer allows sending messages to a remote cache using the HotRod protocol. The consumer allows listening for events from a remote cache using the HotRod protocol.

51.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

51.3.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).
- directly in the Java code.

51.3.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

51.4. COMPONENT OPTIONS

The Infinispan component supports 26 options, which are listed below.

Name	Description	Default	Type
configuration (common)	Component configuration.		InfinispanRemote Configuration
hosts (common)	Specifies the host of the cache on Infinispan instance.		String
queryBuilder (common)	Specifies the query builder.		InfinispanQueryBu ilder
secure (common)	Define if we are connecting to a secured Infinispan instance.	false	boolean
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
customListener (consumer)	Returns the custom listener in use, if provided.		InfinispanRemote CustomListener

Name	Description	Default	Type
eventTypes (consumer)	Specifies the set of event types to register by the consumer. Multiple event can be separated by comma. The possible event types are: CLIENT_CACHE_ENTRY_CREATED, CLIENT_CACHE_ENTRY_MODIFIED, CLIENT_CACHE_ENTRY_REMOVED, CLIENT_CACHE_ENTRY_EXPIRED, CLIENT_CACHE_FAILOVER.		String
defaultValue (producer)	Set a specific default value for some producer operations.		Object
key (producer)	Set a specific key for producer operations.		Object
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
oldValue (producer)	Set a specific old value for some producer operations.		Object

Name	Description	Default	Type
operation (producer)	The operation to perform. Enum values: • PUT • PUTASYNC • PUTALL • PUTALLASYNC • PUTIFABSENT • PUTIFABSENTASYNC • GET • GETORDEFAULT • CONTAINSKEY • CONTAINSVALUE • REMOVE • REMOVEASYNC • REPLACE • REPLACEASYNC • SIZE • CLEAR • CLEARASYNC • QUERY • STATS • COMPUTE • COMPUTEASYNC	PUT	InfinispanOperation
value (producer)	Set a specific value for producer operations.		Object
password (security)	Define the password to access the infinispan instance.		String
saslMechanism (security)	Define the SASL Mechanism to access the infinispan instance.		String

Name	Description	Default	Type
securityRealm (security)	Define the security realm to access the infinispn instance.		String
securityServerName (security)	Define the security server name to access the infinispn instance.		String
username (security)	Define the username to access the infinispn instance.		String
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
cacheContainer (advanced)	Autowired Specifies the cache Container to connect.		RemoteCacheManager
cacheContainerConfiguration (advanced)	Autowired The CacheContainer configuration. Used if the cacheContainer is not defined.		Configuration
configurationProperties (advanced)	Implementation specific properties for the CacheManager.		Map
configurationUri (advanced)	An implementation specific URI for the CacheManager.		String
flags (advanced)	A comma separated list of org.infinispn.client.hotrod.Flag to be applied by default on each cache invocation.		String
remappingFunction (advanced)	Set a specific remappingFunction to use in a compute operation.		BiFunction
resultHeader (advanced)	Store the operation result in a header instead of the message body. By default, resultHeader == null and the query result is stored in the message body, any existing content in the message body is discarded. If resultHeader is set, the value is used as the name of the header to store the query result and the original message body is preserved. This value can be overridden by an in message header named: CamelInfinispnOperationResultHeader.		String

51.5. ENDPOINT OPTIONS

The Infinispan endpoint is configured using URI syntax:

```
infinispan:cacheName
```

with the following path and query parameters:

51.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
cacheName (common)	Required The name of the cache to use. Use current to use the existing cache name from the currently configured cached manager. Or use default for the default cache manager name.		String

51.5.2. Query Parameters (26 parameters)

Name	Description	Default	Type
hosts (common)	Specifies the host of the cache on Infinispan instance.		String
queryBuilder (common)	Specifies the query builder.		InfinispanQueryBuilder
secure (common)	Define if we are connecting to a secured Infinispan instance.	false	boolean
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
customListener (consumer)	Returns the custom listener in use, if provided.		InfinispanRemoteCustomListener

Name	Description	Default	Type
eventTypes (consumer)	Specifies the set of event types to register by the consumer. Multiple event can be separated by comma. The possible event types are: CLIENT_CACHE_ENTRY_CREATED, CLIENT_CACHE_ENTRY_MODIFIED, CLIENT_CACHE_ENTRY_REMOVED, CLIENT_CACHE_ENTRY_EXPIRED, CLIENT_CACHE_FAILOVER.		String
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: ● InOnly ● InOut ● InOptionalOut		ExchangePattern
defaultValue (producer)	Set a specific default value for some producer operations.		Object
key (producer)	Set a specific key for producer operations.		Object
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
oldValue (producer)	Set a specific old value for some producer operations.		Object

Name	Description	Default	Type
operation (producer)	The operation to perform. Enum values: • PUT • PUTASYNC • PUTALL • PUTALLASYNC • PUTIFABSENT • PUTIFABSENTASYNC • GET • GETORDEFAULT • CONTAINSKEY • CONTAINSVALUE • REMOVE • REMOVEASYNC • REPLACE • REPLACEASYNC • SIZE • CLEAR • CLEARASYNC • QUERY • STATS • COMPUTE • COMPUTEASYNC	PUT	InfinispanOperation
value (producer)	Set a specific value for producer operations.		Object
password (security)	Define the password to access the infinispan instance.		String
saslMechanism (security)	Define the SASL Mechanism to access the infinispan instance.		String

Name	Description	Default	Type
securityRealm (security)	Define the security realm to access the infinispn instance.		String
securityServerName (security)	Define the security server name to access the infinispn instance.		String
username (security)	Define the username to access the infinispn instance.		String
cacheContainer (advanced)	Autowired Specifies the cache Container to connect.		RemoteCacheManager
cacheContainerConfiguration (advanced)	Autowired The CacheContainer configuration. Used if the cacheContainer is not defined.		Configuration
configurationProperties (advanced)	Implementation specific properties for the CacheManager.		Map
configurationUri (advanced)	An implementation specific URI for the CacheManager.		String
flags (advanced)	A comma separated list of org.infinispn.client.hotrod.Flag to be applied by default on each cache invocation.		String
remappingFunction (advanced)	Set a specific remappingFunction to use in a compute operation.		BiFunction
resultHeader (advanced)	Store the operation result in a header instead of the message body. By default, resultHeader == null and the query result is stored in the message body, any existing content in the message body is discarded. If resultHeader is set, the value is used as the name of the header to store the query result and the original message body is preserved. This value can be overridden by an in message header named: CamelInfinispnOperationResultHeader.		String

51.6. CAMEL OPERATIONS

This section lists all available operations, along with their header information.

Table 51.1. Table 1. Put Operations

Operation Name	Description
InfinispanOperation.PUT	Puts a key/value pair in the cache, optionally with expiration
InfinispanOperation.PUTASYNC	Asynchronously puts a key/value pair in the cache, optionally with expiration
InfinispanOperation.PUTIFABSENT	Puts a key/value pair in the cache if it did not exist, optionally with expiration
InfinispanOperation.PUTIFABSENTASYNC	Asynchronously puts a key/value pair in the cache if it did not exist, optionally with expiration

- **Required Headers:**
 - CamelInfinispanKey
 - CamelInfinispanValue
- **Optional Headers:**
 - CamelInfinispanLifespanTime
 - CamelInfinispanLifespanTimeUnit
 - CamelInfinispanMaxIdleTime
 - CamelInfinispanMaxIdleTimeUnit
- **Result Header:**
 - CamelInfinispanOperationResult

Table 51.2. Table 2. Put All Operations

Operation Name	Description
InfinispanOperation.PUTALL	Adds multiple entries to a cache, optionally with expiration
CamelInfinispanOperation.PUTALLASYNC	Asynchronously adds multiple entries to a cache, optionally with expiration

- **Required Headers:**
 - CamelInfinispanMap
- **Optional Headers:**
 - CamelInfinispanLifespanTime
 - CamelInfinispanLifespanTimeUnit
 - CamelInfinispanMaxIdleTime

- `CamelInfinispanMaxIdleTimeUnit`

Table 51.3. Table 3. Get Operations

Operation Name	Description
<code>InfinispanOperation.GET</code>	Retrieves the value associated with a specific key from the cache
<code>InfinispanOperation.GETORDEFAULT</code>	Retrieves the value, or default value, associated with a specific key from the cache

- **Required Headers:**
 - `CamelInfinispanKey`

Table 51.4. Table 4. Contains Key Operation

Operation Name	Description
<code>InfinispanOperation.CONTAINSKEY</code>	Determines whether a cache contains a specific key

- **Required Headers**
 - `CamelInfinispanKey`
- **Result Header**
 - `CamelInfinispanOperationResult`

Table 51.5. Table 5. Contains Value Operation

Operation Name	Description
<code>InfinispanOperation.CONTAINSVALUE</code>	Determines whether a cache contains a specific value

- **Required Headers:**
 - `CamelInfinispanKey`

Table 51.6. Table 6. Remove Operations

Operation Name	Description
<code>InfinispanOperation.REMOVE</code>	Removes an entry from a cache, optionally only if the value matches a given one
<code>InfinispanOperation.REMOVEASYNC</code>	Asynchronously removes an entry from a cache, optionally only if the value matches a given one

- **Required Headers:**

- CamelInfinispanKey
- **Optional Headers:**
 - CamelInfinispanValue
- **Result Header:**
 - CamelInfinispanOperationResult

Table 51.7. Table 7. Replace Operations

Operation Name	Description
InfinispanOperation.REPLACE	Conditionally replaces an entry in the cache, optionally with expiration
InfinispanOperation.REPLACEASYNC	Asynchronously conditionally replaces an entry in the cache, optionally with expiration

- **Required Headers:**
 - CamelInfinispanKey
 - CamelInfinispanValue
 - CamelInfinispanOldValue
- **Optional Headers:**
 - CamelInfinispanLifespanTime
 - CamelInfinispanLifespanTimeUnit
 - CamelInfinispanMaxIdleTime
 - CamelInfinispanMaxIdleTimeUnit
- **Result Header:**
 - CamelInfinispanOperationResult

Table 51.8. Table 8. Clear Operations

Operation Name	Description
InfinispanOperation.CLEAR	Clears the cache
InfinispanOperation.CLEARASYNC	Asynchronously clears the cache

Table 51.9. Table 9. Size Operation

Operation Name	Description
InfinispanOperation.SIZE	Returns the number of entries in the cache

- **Result Header**
 - CamelInfinispanOperationResult

Table 51.10. Table 10. Stats Operation

Operation Name	Description
InfinispanOperation.STATS	Returns statistics about the cache

- **Result Header:**
 - CamelInfinispanOperationResult

Table 51.11. Table 11. Query Operation

Operation Name	Description
InfinispanOperation.QUERY	Executes a query on the cache

- **Required Headers:**
 - CamelInfinispanQueryBuilder
- **Result Header:**
 - CamelInfinispanOperationResult

**NOTE**

Write methods like `put(key, value)` and `remove(key)` do not return the previous value by default.

51.7. MESSAGE HEADERS

Name	Default Value	Type	Context	Description
CamelInfinispanCacheName	null	String	Shared	The cache participating in the operation or event.
CamelInfinispanOperation	PUT	InfinispanOperation	Producer	The operation to perform.

Name	Default Value	Type	Context	Description
CamelInfinispanMap	null	Map	Producer	A Map to use in case of CamelInfinispanOperationPutAll operation
CamelInfinispanKey	null	Object	Shared	The key to perform the operation to or the key generating the event.
CamelInfinispanValue	null	Object	Producer	The value to use for the operation.
CamelInfinispanEventType	null	String	Consumer	The type of the received event.
CamelInfinispanLifespanTime	null	long	Producer	The Lifespan time of a value inside the cache. Negative values are interpreted as infinity.
CamelInfinispanTimeUnit	null	String	Producer	The Time Unit of an entry Lifespan Time.
CamelInfinispanMaxIdleTime	null	long	Producer	The maximum amount of time an entry is allowed to be idle for before it is considered as expired.
CamelInfinispanMaxIdleTimeUnit	null	String	Producer	The Time Unit of an entry Max Idle Time.
CamelInfinispanQueryBuilder	null	InfinispanQueryBuilder	Producer	The QueryBuilde to use for QUERY command, if not present the command defaults to InifinispanConfiguration's one
CamelInfinispanOperationResultHeader	null	String	Producer	Store the operation result in a header instead of the message body

51.8. EXAMPLES

- Put a key/value into a named cache:

```
from("direct:start")
  .setHeader(InfinispanConstants.OPERATION).constant(InfinispanOperation.PUT) (1)
  .setHeader(InfinispanConstants.KEY).constant("123") (2)
  .to("infinispan:myCacheName&cacheContainer=#cacheContainer"); (3)
```

Where,

- 1 - Set the operation to perform
- 2 - Set the key used to identify the element in the cache
- 3 - Use the configured cache manager **cacheContainer** from the registry to put an element to the cache named **myCacheName**

It is possible to configure the lifetime and/or the idle time before the entry expires and gets evicted from the cache, as example:

```
from("direct:start")
    .setHeader(InfinispanConstants.OPERATION).constant(InfinispanOperation.GET)
    .setHeader(InfinispanConstants.KEY).constant("123")
    .setHeader(InfinispanConstants.LIFESPAN_TIME).constant(100L) (1)

    .setHeader(InfinispanConstants.LIFESPAN_TIME_UNIT).constant(TimeUnit.MILLISECONDS.toString()) (2)
    .to("infinispan:myCacheName");
```

where,

- 1 - Set the lifespan of the entry
- 2 - Set the time unit for the lifespan

Queries

```
from("direct:start")
    .setHeader(InfinispanConstants.OPERATION, InfinispanConstants.QUERY)
    .setHeader(InfinispanConstants.QUERY_BUILDER, new InfinispanQueryBuilder() {
        @Override
        public Query build(QueryFactory<Query> qf) {
            return qf.from(User.class).having("name").like("%abc%").build();
        }
    })
    .to("infinispan:myCacheName?cacheContainer=#cacheManager") ;
```

NOTE

The .proto descriptors for domain objects must be registered with the remote Data Grid server, see [Remote Query Example](#) in the official Infinispan documentation.

Custom Listeners

```
from("infinispan://?cacheContainer=#cacheManager&customListener=#myCustomListener")
    .to("mock:result");
```

The instance of **myCustomListener** must exist and Camel should be able to look it up from the **Registry**. Users are encouraged to extend the **org.apache.camel.component.infinispan.remote.InfinispanRemoteCustomListener** class and annotate the resulting class with **@ClientListener** which can be found in package **org.infinispan.client.hotrod.annotation**.

51.9. USING THE INFINISPAN BASED IDEMPOTENT REPOSITORY

In this section we will use the Infinispan based idempotent repository.

Java Example

```
InfinispanRemoteConfiguration conf = new InfinispanRemoteConfiguration(); (1)
conf.setHosts("localhost:11222")

InfinispanRemoteldempotentRepository repo = new
InfinispanRemoteldempotentRepository("idempotent"); (2)
repo.setConfiguration(conf);

context.addRoutes(new RouteBuilder() {
    @Override
    public void configure() {
        from("direct:start")
            .idempotentConsumer(header("MessageID"), repo) (3)
            .to("mock:result");
    }
});
```

where,

- 1 - Configure the cache
- 2 - Configure the repository bean
- 3 - Set the repository to the route

XML Example

```
<bean id="infinispanRepo"
class="org.apache.camel.component.infinispan.remote.InfinispanRemoteldempotentRepository"
destroy-method="stop">
    <constructor-arg value="idempotent"/> (1)
    <property name="configuration"> (2)
        <bean class="org.apache.camel.component.infinispan.remote.InfinispanRemoteConfiguration">
            <property name="hosts" value="localhost:11222"/>
        </bean>
    </property>
</bean>

<camelContext xmlns="http://camel.apache.org/schema/spring">
    <route>
        <from uri="direct:start" />
        <idempotentConsumer messageIdRepositoryRef="infinispanRepo"> (3)
            <header>MessageID</header>
            <to uri="mock:result" />
        </idempotentConsumer>
    </route>
</camelContext>
```

where,

- 1 - Set the name of the cache that will be used by the repository
- 2 - Configure the repository bean
- 3 - Set the repository to the route

51.10. USING THE INFINISPAN BASED AGGREGATION REPOSITORY

In this section we will use the Infinispan based aggregation repository.

Java Example

```
InfinispanRemoteConfiguration conf = new InfinispanRemoteConfiguration(); (1)
conf.setHosts("localhost:11222")

InfinispanRemoteAggregationRepository repo = new InfinispanRemoteAggregationRepository(); (2)
repo.setCacheName("aggregation");
repo.setConfiguration(conf);

context.addRoutes(new RouteBuilder() {
    @Override
    public void configure() {
        from("direct:start")
            .aggregate(header("MessageID"))
            .completionSize(3)
            .aggregationRepository(repo) (3)
            .aggregationStrategyRef("myStrategy")
            .to("mock:result");
    }
});
```

where,

- 1 - Configure the cache
- 2 - Create the repository bean
- 3 - Set the repository to the route

XML Example

```
<bean id="infinispanRepo"
class="org.apache.camel.component.infinispan.remote.InfinispanRemoteAggregationRepository"
destroy-method="stop">
    <constructor-arg value="aggregation"/> (1)
    <property name="configuration"> (2)
        <bean class="org.apache.camel.component.infinispan.remote.InfinispanRemoteConfiguration">
            <property name="hosts" value="localhost:11222"/>
        </bean>
    </property>
</bean>

<camelContext xmlns="http://camel.apache.org/schema/spring">
    <route>
        <from uri="direct:start" />
```

```

<aggregate strategyRef="myStrategy"
  completionSize="3"
  aggregationRepositoryRef="infinispanRepo"> (3)
  <correlationExpression>
    <header>MessageID</header>
  </correlationExpression>
  <to uri="mock:result"/>
</aggregate>
</route>
</camelContext>

```

where,

- 1 - Set the name of the cache that will be used by the repository
- 2 - Configure the repository bean
- 3 - Set the repository to the route

NOTE

With the release of Infinispan 11, it is required to set the encoding configuration on any cache created. This is critical for consuming events too. For more information have a look at [Data Encoding and MediaTypes](#) in the official Infinispan documentation.

51.11. SPRING BOOT AUTO-CONFIGURATION

The component supports 23 options, which are listed below.

Name	Description	Default	Type
camel.component.infinispan.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.infinispan.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean

Name	Description	Default	Type
<code>camel.component.infinispan.cache-container</code>	Specifies the cache Container to connect. The option is a <code>org.infinispan.client.hotrod.RemoteCacheManager</code> type.		<code>RemoteCacheManager</code>
<code>camel.component.infinispan.cache-container-configuration</code>	The <code>CacheContainer</code> configuration. Used if the <code>cacheContainer</code> is not defined. The option is a <code>org.infinispan.client.hotrod.configuration.Configuration</code> type.		<code>Configuration</code>
<code>camel.component.infinispan.configuration</code>	Component configuration. The option is a <code>org.apache.camel.component.infinispan.remote.InfinispanRemoteConfiguration</code> type.		<code>InfinispanRemoteConfiguration</code>
<code>camel.component.infinispan.configuration-properties</code>	Implementation specific properties for the <code>CacheManager</code> .		<code>Map</code>
<code>camel.component.infinispan.configuration-uri</code>	An implementation specific URI for the <code>CacheManager</code> .		<code>String</code>
<code>camel.component.infinispan.custom-listener</code>	Returns the custom listener in use, if provided. The option is a <code>org.apache.camel.component.infinispan.remote.InfinispanRemoteCustomListener</code> type.		<code>InfinispanRemoteCustomListener</code>
<code>camel.component.infinispan.enabled</code>	Whether to enable auto configuration of the <code>infinispan</code> component. This is enabled by default.		<code>Boolean</code>
<code>camel.component.infinispan.event-types</code>	Specifies the set of event types to register by the consumer. Multiple event can be separated by comma. The possible event types are: <code>CLIENT_CACHE_ENTRY_CREATED</code> , <code>CLIENT_CACHE_ENTRY_MODIFIED</code> , <code>CLIENT_CACHE_ENTRY_REMOVED</code> , <code>CLIENT_CACHE_ENTRY_EXPIRED</code> , <code>CLIENT_CACHE_FAILOVER</code> .		<code>String</code>
<code>camel.component.infinispan.flags</code>	A comma separated list of <code>org.infinispan.client.hotrod.Flag</code> to be applied by default on each cache invocation.		<code>String</code>
<code>camel.component.infinispan.hosts</code>	Specifies the host of the cache on <code>Infinispan</code> instance.		<code>String</code>

Name	Description	Default	Type
camel.component.infinispan.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.infinispan.operation	The operation to perform.		InfinispanOperation
camel.component.infinispan.password	Define the password to access the infinispan instance.		String
camel.component.infinispan.query-builder	Specifies the query builder. The option is a org.apache.camel.component.infinispan.InfinispanQueryBuilder type.		InfinispanQueryBuilder
camel.component.infinispan.remapping-function	Set a specific remappingFunction to use in a compute operation. The option is a java.util.function.BiFunction type.		BiFunction
camel.component.infinispan.result-header	Store the operation result in a header instead of the message body. By default, resultHeader == null and the query result is stored in the message body, any existing content in the message body is discarded. If resultHeader is set, the value is used as the name of the header to store the query result and the original message body is preserved. This value can be overridden by an in message header named: CamelInfinispanOperationResultHeader.		String
camel.component.infinispan.sasl-mechanism	Define the SASL Mechanism to access the infinispan instance.		String
camel.component.infinispan.secure	Define if we are connecting to a secured Infinispan instance.	false	Boolean

Name	Description	Default	Type
<code>camel.component.infinispan.security-realm</code>	Define the security realm to access the infinispan instance.		String
<code>camel.component.infinispan.security-server-name</code>	Define the security server name to access the infinispan instance.		String
<code>camel.component.infinispan.username</code>	Define the username to access the infinispan instance.		String

CHAPTER 52. INFINISPAN EMBEDDED

Since Camel 2.13

Both producer and consumer are supported

This component allows you to interact with [Infinispan](#) distributed data grid / cache. Infinispan is an extremely scalable, highly available key / value data store and data grid platform written in Java.

The **camel-infinispan-embedded** component includes the following features.

- **Local Camel Consumer** - Receives cache change notifications and sends them to be processed. This can be done synchronously or asynchronously, and is also supported with a replicated or distributed cache.
- **Local Camel Producer** - A producer creates and sends messages to an endpoint. The **camel-infinispan** producer uses **GET**, **PUT**, **REMOVE**, and **CLEAR** operations. The local producer is also supported with a replicated or distributed cache.

The events are processed asynchronously.

52.1. DEPENDENCIES

When using **infinispan-embedded** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-infinispan-embedded-starter</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

52.2. URI FORMAT

```
infinispan-embedded://cacheName?[options]
```

The producer allows sending messages to a local infinispan cache. The consumer allows listening for events from local infinispan cache.

If no cache configuration is provided, embedded cacheContainer is created directly in the component.

52.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

52.3.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the

endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).
- directly in the Java code.

52.3.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

52.4. COMPONENT OPTIONS

The Infinispan Embedded component supports 20 options that are listed below.

Name	Description	Default	Type
configuration (common)	Component configuration.		InfinispanEmbeddedCon figuration
queryBuilder (common)	Specifies the query builder.		InfinispanQueryBuilder

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
clusteredListener (consumer)	If true, the listener will be installed for the entire cluster.	false	boolean
customListener (consumer)	Returns the custom listener in use, if provided.		<code>InfinispanEmbeddedCustomListener</code>

Name	Description	Default	Type
eventTypes (consumer)	Specifies the set of event types to register by the consumer. Multiple event can be separated by comma. The possible event types are: CACHE_ENTRY_ACTIVATED, CACHE_ENTRY_PASIVATED, CACHE_ENTRY_VISITED, CACHE_ENTRY_LOADED, CACHE_ENTRY_EVICTED, CACHE_ENTRY_CREATED, CACHE_ENTRY_REMOVED, CACHE_ENTRY_MODIFIED, TRANSACTION_COMPLETED, TRANSACTION_REGISTERED, CACHE_ENTRY_INVALIDATED, CACHE_ENTRY_EXPIRED, DATA_REHASHED, TOPOLOGY_CHANGED, PARTITION_STATUS_CHANGED, PERSISTENCE_AVAILABILITY_CHANGED.		String
sync (consumer)	If true, the consumer will receive notifications synchronously.	true	boolean
defaultValue (producer)	Set a specific default value for some producer operations.		Object
key (producer)	Set a specific key for producer operations.		Object

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
oldValue (producer)	Set a specific old value for some producer operations.		Object
operation (producer)	The operation to perform. Enum values: * PUT * PUTASYNC * PUTALL * PUTALLASYNC * PUTIFABSENT * PUTIFABSENTASYNC * GET * GETORDEFAULT * * CONTAINSKEY * CONTAINSVALUE * REMOVE * REMOVEASYNC * REPLACE * REPLACEASYNC * SIZE * * CLEAR * CLEARASYNC * QUERY * * STATS * COMPUTE * COMPUTEASYNC	PUT	InfinispanOperation

Name	Description	Default	Type
value* (producer)	Set a specific value for producer operations.		Object
autowiredEnabled (advanced)	Whether auto-wiring is enabled. This is used for automatic auto-wiring options (the option must be marked as auto-wired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
cacheContainer (advanced)	Autowired Specifies the cache Container to connect.		EmbeddedCacheManager
cacheContainerConfiguration (advanced)	Autowired The CacheContainer configuration. Used if the cacheContainer is not defined.		Configuration
configurationUri (advanced)	An implementation specific URI for the CacheManager.		String
flags (advanced)	A comma separated list of org.infinispan.context.Flag to be applied by default on each cache invocation.		String
remappingFunction (advanced)	Set a specific remappingFunction to use in a compute operation.		BiFunction

Name	Description	Default	Type
resultHeader (advanced)	Store the operation result in a header instead of the message body. By default, resultHeader == null and the query result is stored in the message body, any existing content in the message body is discarded. If resultHeader is set, the value is used as the name of the header to store the query result and the original message body is preserved. This value can be overridden by an in message header named: CamelInfinispanOperationResultHeader.		String

52.5. ENDPOINT OPTIONS

The Infinispan Embedded endpoint is configured using URI syntax.

`infinispan-embedded:cacheName`

Following are the path and query parameters.

52.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
cacheName (common)	Required The name of the cache to use. Use current to use the existing cache name from the currently configured cached manager. Or use default for the default cache manager name.		String

52.5.2. Query Parameters (20 parameters)

Name	Description	Default	Type
queryBuilder (common)	Specifies the query builder.		InfinispanQueryBuilder
clusteredListener (consumer)	If true, the listener will be installed for the entire cluster.	false	boolean
customListener (consumer)	Returns the custom listener in use, if provided.		InfinispanEmbeddedCustomListener
eventTypes (consumer)	Specifies the set of event types to register by the consumer. Multiple event can be separated by comma. The possible event types are: CACHE_ENTRY_ACTIVATED, CACHE_ENTRY_PASIVATED, CACHE_ENTRY_VISITED, CACHE_ENTRY_LOADED, CACHE_ENTRY_EVICTED, CACHE_ENTRY_CREATED, CACHE_ENTRY_REMOVED, CACHE_ENTRY_MODIFIED, TRANSACTION_COMPLETED, TRANSACTION_REGISTERED, CACHE_ENTRY_INVALIDATED, CACHE_ENTRY_EXPIRED, DATA_REHASHED, TOPOLOGY_CHANGED, PARTITION_STATUS_CHANGED, PERSISTENCE_AVAILABILITY_CHANGED.		String

Name	Description	Default	Type
sync (consumer)	If true, the consumer will receive notifications synchronously.	true	boolean
bridgeErrorHandler (consumer (advanced))	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer (advanced))	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		<code>ExceptionHandler</code>
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: * InOnly * InOut * InOptionalOut		<code>ExchangePattern</code>

Name	Description	Default	Type
defaultValue (producer)	Set a specific default value for some producer operations.		Object
key (producer)	Set a specific key for producer operations.		Object
oldValue (producer)	Set a specific old value for some producer operations.		Object
operation (producer)	The operation to perform. Enum values: * PUT * PUTASYNC * PUTALL * PUTALLASYNC * PUTIFABSENT * PUTIFABSENTASYNC * GET * GETORDEFAULT * * CONTAINSKEY * CONTAINSVALUE * REMOVE * REMOVEASYNC * REPLACE * REPLACEASYNC * SIZE * CLEAR * CLEARASYNC * QUERY * STATS * COMPUTE * COMPUTEASYNC	PUT	InfinispanOperation
value (producer)	Set a specific value for producer operations.		Object

Name	Description	Default	Type
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
cacheContainer (advanced)	Autowired Specifies the cache Container to connect.		EmbeddedCacheManager
cacheContainerConfiguration (advanced)	Autowired The CacheContainer configuration. Used if the cacheContainer is not defined.		Configuration
configurationUri (advanced)	An implementation specific URI for the CacheManager.		String
flags (advanced)	A comma separated list of org.infinispan.context.Flag to be applied by default on each cache invocation.		String

Name	Description	Default	Type
remappingFunction (advanced)	Set a specific remappingFunction to use in a compute operation.		BiFunction
resultHeader (advanced)	Store the operation result in a header instead of the message body. By default, resultHeader == null and the query result is stored in the message body, any existing content in the message body is discarded. If resultHeader is set, the value is used as the name of the header to store the query result and the original message body is preserved. This value can be overridden by an in message header named: CamelInfinispanOperationResultHeader.		String

52.6. MESSAGE HEADERS

The Infinispan Embedded component supports 22 message headers that are listed below.

Name	Description	Default	Type
CamelInfinispanEventType (consumer) Constant: EVENT_TYPE	The type of the received event.		String
CamelInfinispanIsPre (consumer) Constant: IS_PRE	true if the notification is before the event has occurred, false if after the event has occurred.		boolean

Name	Description	Default	Type
CamelInfinispanCacheName (common) Constant: CACHE_NAME	The cache participating in the operation or event.		String
CamelInfinispanKey (common) Constant: KEY	The key to perform the operation to or the key generating the event.		Object
CamelInfinispanValue (producer) Constant: VALUE	The value to use for the operation.		Object
CamelInfinispanDefaultValue (producer) Constant: DEFAULT_VALUE	The default value to use for a getOrDefault.		Object
CamelInfinispanOldValue (producer) Constant: OLD_VALUE	The old value to use for a replace.		Object
CamelInfinispanMap (producer) Constant: MAP	A Map to use in case of CamelInfinispanOperationPutAll operation.		Map

Name	Description	Default	Type
CamelInfinispanOperation (producer) Constant: OPERATION	The operation to perform. Enum values: * PUT * PUTASYNC * PUTALL * PUTALLASYNC * PUTIFABSENT * PUTIFABSENTASYNC * GET * GETORDEFAULT * * CONTAINSKEY * CONTAINSVALUE * REMOVE * REMOVEASYNC * REPLACE * REPLACEASYNC * SIZE * * CLEAR * CLEARASYNC * QUERY * * STATS * COMPUTE * COMPUTEASYNC		InfinispanOperation
CamelInfinispanOperationResult (producer) Constant: RESULT	The name of the header whose value is the result.		String
CamelInfinispanOperationResultHeader (producer) Constant: RESULT_HEADER	Store the operation result in a header instead of the message body.		String
CamelInfinispanLifespanTime (producer) Constant: LIFESPAN_TIME	The Lifespan time of a value inside the cache. Negative values are interpreted as infinity.		long
CamelInfinispanTimeUnit (producer) Constant: LIFESPAN_TIME_UNIT	The Time Unit of an entry Lifespan Time. Enum values: * NANoseconds * MICROSECONDS * MILLISECONDs * SECONDS * MINUTES * HOURS * DAYS		TimeUnit

Name	Description	Default	Type
CamelInfinispanMaxIdleTime (producer) Constant: MAX_IDLE_TIME	The maximum amount of time an entry is allowed to be idle for before it is considered as expired.		long
CamelInfinispanMaxIdleTimeUnit (producer) Constant: MAX_IDLE_TIME_UNIT	The Time Unit of an entry Max Idle Time. Enum values: * NANoseconds * MICROseconds * MILLIseconds * SECONDS * MINUTES * HOURS * DAYS		TimeUnit
CamelInfinispanIgnoreReturnValues (consumer) Constant: IGNORE_RETURN_VALUES	Signals that write operation's return value are ignored, so reading the existing value from a store or from a remote node is not necessary.	false	boolean
CamelInfinispanEventData (consumer) Constant: EVENT_DATA	The event data.		Object
CamelInfinispanQueryBuilder (producer) Constant: QUERY_BUILDER	The QueryBuilder to use for QUERY command, if not present the command defaults to InfinispanConfiguration's one.		InfinispanQueryBuilder
CamelInfinispanCommandRetried (consumer) Constant: COMMAND_RETRIED	This will be true if the write command that caused this had to be retried again due to a topology change.		boolean
CamelInfinispanEntryCreated (consumer) Constant: ENTRY_CREATED	Indicates whether the cache entry modification event is the result of the cache entry being created.		boolean

Name	Description	Default	Type
CamelInfinispanOriginLocal (consumer) Constant: ORIGIN_LOCAL	true if the call originated on the local cache instance; false if originated from a remote one.		boolean
CamelInfinispanCurrentState (consumer) Constant: CURRENT_STATE	True if this event is generated from an existing entry as the listener has Listener.		boolean

52.7. CAMEL OPERATIONS

This section lists all available operations along with their header information.

Table 52.1. Table 1. Put Operations

Operation Name	Description
InfinispanOperation.PUT	Puts a key/value pair in the cache, optionally with expiration
InfinispanOperation.PUTASYNC	Asynchronously puts a key/value pair in the cache, optionally with expiration
InfinispanOperation.PUTIFABSENT	Puts a key/value pair in the cache if it did not exist, optionally with expiration
InfinispanOperation.PUTIFABSENTASYNC	Asynchronously puts a key/value pair in the cache if it did not exist, optionally with expiration

- **Required Headers:**
 - CamelInfinispanKey
 - CamelInfinispanValue
- **Optional Headers:**
 - CamelInfinispanLifespanTime
 - CamelInfinispanLifespanTimeUnit
 - CamelInfinispanMaxIdleTime
 - CamelInfinispanMaxIdleTimeUnit
- **Result Header:**
 - CamelInfinispanOperationResult

– CamelInfinispanOperationResult

Table 52.2. Table 2. Put All Operations

Operation Name	Description
InfinispanOperation.PUTALL	Adds multiple entries to a cache, optionally with expiration
CamelInfinispanOperation.PUTALLASYNC	Asynchronously adds multiple entries to a cache, optionally with expiration

- **Required Headers:**
 - CamelInfinispanMap
- **Optional Headers:**
 - CamelInfinispanLifespanTime
 - CamelInfinispanLifespanTimeUnit
 - CamelInfinispanMaxIdleTime
 - CamelInfinispanMaxIdleTimeUnit

Table 52.3. Table 3. Get Operations

Operation Name	Description
InfinispanOperation.GET	Retrieves the value associated with a specific key from the cache
InfinispanOperation.GETORDEFAULT	Retrieves the value, or default value, associated with a specific key from the cache

- **Required Headers:**
 - CamelInfinispanKey

Table 52.4. Table 4. Contains Key Operation

Operation Name	Description
InfinispanOperation.CONTAINSKEY	Determines whether a cache contains a specific key

- **Required Headers**
 - CamelInfinispanKey
- **Result Header**
 - CamelInfinispanOperationResult

Table 52.5. Table 5. Contains Value Operation

Operation Name	Description
InfinispanOperation.CONTAINSVALUE	Determines whether a cache contains a specific value

- **Required Headers:**
 - CamelInfinispanKey

Table 52.6. Table 6. Remove Operations

Operation Name	Description
InfinispanOperation.REMOVE	Removes an entry from a cache, optionally only if the value matches a given one
InfinispanOperation.REMOVEASYNC	Asynchronously removes an entry from a cache, optionally only if the value matches a given one

- **Required Headers:**
 - CamelInfinispanKey
- **Optional Headers:**
 - CamelInfinispanValue
- **Result Header:**
 - CamelInfinispanOperationResult

Table 52.7. Table 7. Replace Operations

Operation Name	Description
InfinispanOperation.REPLACE	Conditionally replaces an entry in the cache, optionally with expiration
InfinispanOperation.REPLACEASYNC	Asynchronously conditionally replaces an entry in the cache, optionally with expiration

- **Required Headers:**
 - CamelInfinispanKey
 - CamelInfinispanValue
 - CamelInfinispanOldValue
- **Optional Headers:**

- `CamellInfinispanLifespanTime`
- `CamellInfinispanLifespanTimeUnit`
- `CamellInfinispanMaxIdleTime`
- `CamellInfinispanMaxIdleTimeUnit`
- **Result Header:**
 - `CamellInfinispanOperationResult`

Table 52.8. Table 8. Clear Operations

Operation Name	Description
<code>InfinispanOperation.CLEAR</code>	Clears the cache
<code>InfinispanOperation.CLEARASYNC</code>	Asynchronously clears the cache

Table 52.9. Table 9. Size Operation

Operation Name	Description
<code>InfinispanOperation.SIZE</code>	Returns the number of entries in the cache

- **Result Header**
 - `CamellInfinispanOperationResult`

Table 52.10. Table 10. Stats Operation

Operation Name	Description
<code>InfinispanOperation.STATS</code>	Returns statistics about the cache

- **Result Header:**
 - `CamellInfinispanOperationResult`

Table 52.11. Table 11. Query Operation

Operation Name	Description
<code>InfinispanOperation.QUERY</code>	Executes a query on the cache

- **Required Headers:**
 - `CamellInfinispanQueryBuilder`
- **Result Header:**

- CamelInfinispanOperationResult

NOTE

Write methods like `put(key, value)` and `remove(key)` do not return the previous value by default.

52.8. EXAMPLES

- Put a key/value into a named cache:

```
from("direct:start")
  .setHeader(InfinispanConstants.OPERATION).constant(InfinispanOperation.PUT) (1)
  .setHeader(InfinispanConstants.KEY).constant("123") (2)
  .to("infinispan:myCacheName&cacheContainer=#cacheContainer"); (3)
```

- Set the operation to perform
- Set the key used to identify the element in the cache
- Use the configured cache manager **cacheContainer** from the registry to put an element to the cache named **myCacheName**
It is possible to configure the lifetime and/or the idle time before the entry expires and gets evicted from the cache, as example.

```
from("direct:start")
  .setHeader(InfinispanConstants.OPERATION).constant(InfinispanOperation.GET)
  .setHeader(InfinispanConstants.KEY).constant("123")
  .setHeader(InfinispanConstants.LIFESPAN_TIME).constant(100L) (1)

  .setHeader(InfinispanConstants.LIFESPAN_TIME_UNIT).constant(TimeUnit.MILLISECONDS.toString()) (2)
  .to("infinispan:myCacheName");
```

- Set the lifespan of the entry
- Set the time unit for the lifespan

- Queries

```
from("direct:start")
  .setHeader(InfinispanConstants.OPERATION, InfinispanConstants.QUERY)
  .setHeader(InfinispanConstants.QUERY_BUILDER, new InfinispanQueryBuilder() {
    @Override
    public Query build(QueryFactory<Query> qf) {
      return qf.from(User.class).having("name").like("%abc%").build();
    }
  })
  .to("infinispan:myCacheName?cacheContainer=#cacheManager");
```

- Custom Listeners

```
from("infinispan://?cacheContainer=#cacheManager&customListener=#myCustomListener")
  .to("mock:result");
```

- The instance of **myCustomListener** must exist and Camel should be able to look it up from the **Registry**. Users are encouraged to extend the **org.apache.camel.component.infinispan.embedded.InfinispanEmbeddedCustomListener** class and annotate the resulting class with **@Listener** which can be found in package **org.infinispan.notifications**.

52.9. USING THE INFINISPAN BASED IDEMPOTENT REPOSITORY

Java Example

```
InfinispanEmbeddedConfiguration conf = new InfinispanEmbeddedConfiguration(); (1)
conf.setConfigurationUri("classpath:infinispan.xml")

InfinispanEmbeddedIdempotentRepository repo = new
InfinispanEmbeddedIdempotentRepository("idempotent"); (2)
repo.setConfiguration(conf);

context.addRoutes(new RouteBuilder() {
    @Override
    public void configure() {
        from("direct:start")
            .idempotentConsumer(header("MessageID"), repo) (3)
            .to("mock:result");
    }
});
```

- Configure the cache
- Configure the repository bean
- Set the repository to the route

XML Example

```
<bean id="infinispanRepo"
class="org.apache.camel.component.infinispan.embedded.InfinispanEmbeddedIdempotentRepository"
destroy-method="stop">
    <constructor-arg value="idempotent"/> (1)
    <property name="configuration"> (2)
        <bean
class="org.apache.camel.component.infinispan.embedded.InfinispanEmbeddedConfiguration">
            <property name="configurationUri" value="classpath:infinispan.xml"/>
        </bean>
    </property>
</bean>

<camelContext xmlns="http://camel.apache.org/schema/spring">
    <route>
        <from uri="direct:start" />
        <idempotentConsumer idempotentRepository="infinispanRepo"> (3)
            <header>MessageID</header>
            <to uri="mock:result" />
        </idempotentConsumer>
    </route>
</camelContext>
```

- Set the name of the cache that will be used by the repository
- Configure the repository bean
- Set the repository to the route

52.10. USING THE INFINISPAN BASED AGGREGATION REPOSITORY

Java Example

```
InfinispanEmbeddedConfiguration conf = new InfinispanEmbeddedConfiguration(); (1)
conf.setConfigurationUri("classpath:infinispan.xml")

InfinispanEmbeddedAggregationRepository repo = new
InfinispanEmbeddedAggregationRepository("aggregation"); (2)
repo.setConfiguration(conf);

context.addRoutes(new RouteBuilder() {
    @Override
    public void configure() {
        from("direct:start")
            .aggregate(header("MessageID"))
            .completionSize(3)
            .aggregationRepository(repo) (3)
            .aggregationStrategy("myStrategy")
            .to("mock:result");
    }
});
```

- Configure the cache
- Create the repository bean
- Set the repository to the route

XML Example

```
<bean id="infinispanRepo"
class="org.apache.camel.component.infinispan.embedded.InfinispanEmbeddedAggregationRepository"
destroy-method="stop">
    <constructor-arg value="aggregation"/> (1)
    <property name="configuration"> (2)
        <bean
class="org.apache.camel.component.infinispan.embedded.InfinispanEmbeddedConfiguration">
            <property name="configurationUri" value="classpath:infinispan.xml"/>
        </bean>
    </property>
</bean>

<camelContext xmlns="http://camel.apache.org/schema/spring">
    <route>
        <from uri="direct:start" />
        <aggregate aggregationStrategy="myStrategy"
            completionSize="3">
```

```

        aggregationRepository="infinispanRepo"> (3)
    <correlationExpression>
        <header>MessageID</header>
    </correlationExpression>
    <to uri="mock:result"/>
</aggregate>
</route>
</camelContext>

```

- Set the name of the cache that will be used by the repository
- Configure the repository bean
- Set the repository to the route

NOTE

With the release of Infinispan 11, it is required to set the encoding configuration on any cache created. This is critical for consuming events too. For more information have a look at [Data Encoding and MediaTypes](#) in the official Infinispan documentation.

52.11. SPRING BOOT AUTO-CONFIGURATION

The component supports 17 options that are listed below.

Name	Description	Default	Type
camel.component.infinispan-embedded.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean

Name	Description	Default	Type
camel.component.infinispan-embedded.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.infinispan-embedded.cache-container	Specifies the cache Container to connect. The option is a <code>org.infinispan.manager.EmbeddedCacheManager</code> type.		<code>EmbeddedCacheManager</code>
camel.component.infinispan-embedded.cache-container-configuration	The <code>CacheContainer</code> configuration. Used if the <code>cacheContainer</code> is not defined. The option is a <code>org.infinispan.configuration.cache.Configuration</code> type.		Configuration
camel.component.infinispan-embedded.clustered-listener	If true, the listener will be installed for the entire cluster.	false	Boolean
camel.component.infinispan-embedded.configuration	Component configuration. The option is a <code>org.apache.camel.component.infinispan.embedded.InfinispanEmbeddedConfiguration</code> type.		<code>InfinispanEmbeddedConfiguration</code>

Name	Description	Default	Type
<code>camel.component.infinispan-embedded.configuration-uri</code>	An implementation specific URI for the CacheManager.		String
<code>camel.component.infinispan-embedded.custom-listener</code>	Returns the custom listener in use, if provided. The option is a <code>org.apache.camel.component.infinispan.embedded.InfinispanEmbeddedCustomListener</code> type.		<code>InfinispanEmbeddedCustomListener</code>
<code>camel.component.infinispan-embedded.enabled</code>	Whether to enable auto configuration of the <code>infinispan-embedded</code> component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.infinispan-embedded.event-types	Specifies the set of event types to register by the consumer. Multiple event can be separated by comma. The possible event types are: CACHE_ENTRY_ACTIVATED, CACHE_ENTRY_PASIVATED, CACHE_ENTRY_VISITED, CACHE_ENTRY_LOADED, CACHE_ENTRY_EVICTED, CACHE_ENTRY_CREATED, CACHE_ENTRY_REMOVED, CACHE_ENTRY_MODIFIED, TRANSACTION_COMPLETED, TRANSACTION_REGISTERED, CACHE_ENTRY_INVALIDATED, CACHE_ENTRY_EXPIRED, DATA_REHASHED, TOPOLOGY_CHANGED, PARTITION_STATUS_CHANGED, PERSISTENCE_AVAILABILITY_CHANGED.		String
camel.component.infinispan-embedded.flags	A comma separated list of org.infinispan.context.Flag to be applied by default on each cache invocation.		String

Name	Description	Default	Type
camel.component.infinispan-embedded.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.infinispan-embedded.operation	The operation to perform.		InfinispanOperation
camel.component.infinispan-embedded.query-builder	Specifies the query builder. The option is a org.apache.camel.component.infinispan.InfinispanQueryBuilder type.		InfinispanQueryBuilder
camel.component.infinispan-embedded.remapping-function	Set a specific remappingFunction to use in a compute operation. The option is a java.util.function.BiFunction type.		BiFunction

Name	Description	Default	Type
camel.component.infinispan-embedded.result-header	Store the operation result in a header instead of the message body. By default, resultHeader == null and the query result is stored in the message body, any existing content in the message body is discarded. If resultHeader is set, the value is used as the name of the header to store the query result and the original message body is preserved. This value can be overridden by an in message header named: CamelInfinispanOperationResultHeader.		String
camel.component.infinispan-embedded.sync	If true, the consumer will receive notifications synchronously.	true	Boolean

CHAPTER 53. JACKSONXML

Jackson XML is a Data Format which uses the [Jackson library](#) with the [XMLMapper extension](#) to unmarshal an XML payload into Java objects or to marshal Java objects into an XML payload. NOTE: If you are familiar with Jackson, this XML data format behaves in the same way as its JSON counterpart, and thus can be used with classes annotated for JSON serialization/deserialization.

This extension also mimics [JAXB's "Code first" approach](#).

This data format relies on [Woodstox](#) (especially for features like pretty printing), a fast and efficient XML processor.

```
from("activemq:My.Queue").
    unmarshal().jacksonxml().
    to("mqseries:Another.Queue");
```

53.1. DEPENDENCIES

When using **jacksonxml** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-jacksonxml-starter</artifactId>
</dependency>
```

53.2. JACKSONXML OPTIONS

The JacksonXML dataformat supports 15 options, which are listed below.

Name	Default	Java Type	Description
xmlMapper		String	Lookup and use the existing XmlMapper with the given id.
prettyPrint	false	Boolean	To enable pretty printing output nicely formatted. Is by default false.
unmarshalType		String	Class name of the java type to use when unmarshalling.
jsonView		String	When marshalling a POJO to JSON you might want to exclude certain fields from the JSON output. With Jackson you can use JSON views to accomplish this. This option is to refer to the class which has JsonView annotations.
include		String	If you want to marshal a pojo to JSON, and the pojo has some fields with null values. And you want to skip these null values, you can set this option to NON_NULL.

Name	Default	Java Type	Description
allowJmsType		Boolean	Used for JMS users to allow the JMSType header from the JMS spec to specify a FQN classname to use to unmarshal to.
collectionType		String	Refers to a custom collection type to lookup in the registry to use. This option should rarely be used, but allows to use different collection types than java.util.Collection based as default.
useList		Boolean	To unmarshal to a List of Map or a List of Pojo.
enableJaxbAnnotationModule		Boolean	Whether to enable the JAXB annotations module when using jackson. When enabled then JAXB annotations can be used by Jackson.
moduleClassNames		String	To use custom Jackson modules com.fasterxml.jackson.databind.Module specified as a String with FQN class names. Multiple classes can be separated by comma.
moduleRefs		String	To use custom Jackson modules referred from the Camel registry. Multiple modules can be separated by comma.
enableFeatures		String	Set of features to enable on the Jackson com.fasterxml.jackson.databind.ObjectMapper. The features should be a name that matches a enum from com.fasterxml.jackson.databind.SerializationFeature, com.fasterxml.jackson.databind.DeserializationFeature, or com.fasterxml.jackson.databind.MapperFeature Multiple features can be separated by comma.
disableFeatures		String	Set of features to disable on the Jackson com.fasterxml.jackson.databind.ObjectMapper. The features should be a name that matches a enum from com.fasterxml.jackson.databind.SerializationFeature, com.fasterxml.jackson.databind.DeserializationFeature, or com.fasterxml.jackson.databind.MapperFeature Multiple features can be separated by comma.
allowUnmarshalType		Boolean	If enabled then Jackson is allowed to attempt to use the CamelJacksonUnmarshalType header during the unmarshalling. This should only be enabled when desired to be used.
contentTypeHeader		Boolean	Whether the data format should set the Content-Type header with the type from the data format. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON.

53.2.1. Using Jackson XML in Spring DSL

When using Data Format in Spring DSL you need to declare the data formats first. This is done in the **DataFormats** XML tag.

```
<dataFormats>
  <!-- here we define a Xml data format with the id jack and that it should use the TestPojo as
the class type when
      doing unmarshal. The unmarshalType is optional, if not provided Camel will use a Map as
the type -->
  <jacksonxml id="jack" unmarshalType="org.apache.camel.component.jacksonxml.TestPojo"/>
</dataFormats>
```

And then you can refer to this id in the route:

```
<route>
  <from uri="direct:back"/>
  <unmarshal><custom ref="jack"/></unmarshal>
  <to uri="mock:reverse"/>
</route>
```

53.2.2. Excluding POJO fields from marshalling

When marshalling a POJO to XML you might want to exclude certain fields from the XML output. With Jackson you can use [JSON views](#) to accomplish this. First create one or more marker classes.

Use the marker classes with the **@JsonView** annotation to include/exclude certain fields. The annotation also works on getters.

Finally use the Camel **JacksonXMLDataFormat** to marshall the above POJO to XML.

Note that the weight field is missing in the resulting XML:

```
<pojo age="30" weight="70"/>
```

53.3. INCLUDE/EXCLUDE FIELDS USING THE JSONVIEW ATTRIBUTE WITH `JACKSONXML` DATAFORMAT

As an example of using this attribute you can instead of:

```
JacksonXMLDataFormat ageViewFormat = new JacksonXMLDataFormat(TestPojoView.class,
Views.Age.class);
from("direct:inPojoAgeView").
  marshal(ageViewFormat);
```

Directly specify your [JSON view](#) inside the Java DSL as:

```
from("direct:inPojoAgeView").
  marshal().jacksonxml(TestPojoView.class, Views.Age.class);
```

And the same in XML DSL:

```
<from uri="direct:inPojoAgeView"/>
<marshal>
  <jacksonxml unmarshalType="org.apache.camel.component.jacksonxml.TestPojoView"
  jsonView="org.apache.camel.component.jacksonxml.Views$Age"/>
</marshal>
```

53.4. SETTING SERIALIZATION INCLUDE OPTION

If you want to marshal a pojo to XML, and the pojo has some fields with null values. And you want to skip these null values, then you need to set either an annotation on the pojo,

```
@JsonInclude(Include.NON_NULL)
public class MyPojo {
    ...
}
```

But this requires you to include that annotation in your pojo source code. You can also configure the Camel JacksonXMLDataFormat to set the include option, as shown below:

```
JacksonXMLDataFormat format = new JacksonXMLDataFormat();
format.setInclude("NON_NULL");
```

Or from XML DSL you configure this as

```
<dataFormats>
  <jacksonxml id="jacksonxml" include="NON_NULL"/>
</dataFormats>
```

53.5. UNMARSHALLING FROM XML TO POJO WITH DYNAMIC CLASS NAME

If you use jackson to unmarshal XML to POJO, then you can now specify a header in the message that indicate which class name to unmarshal to.

The header has key **CamelJacksonUnmarshalType** if that header is present in the message, then Jackson will use that as FQN for the POJO class to unmarshal the XML payload as.

For JMS end users there is the JMSType header from the JMS spec that indicates that also. To enable support for JMSType you would need to turn that on, on the jackson data format as shown:

```
JacksonDataFormat format = new JacksonDataFormat();
format.setAllowJmsType(true);
```

Or from XML DSL you configure this as

```
<dataFormats>
  <jacksonxml id="jacksonxml" allowJmsType="true"/>
</dataFormats>
```

53.6. UNMARSHALLING FROM XML TO LIST<MAP> OR LIST<POJO>

If you are using Jackson to unmarshal XML to a list of map/pojo, you can now specify this by setting **useList="true"** or use the **org.apache.camel.component.jacksonxml.ListJacksonXMLDataFormat**. For example with Java you can do as shown below:

```
JacksonXMLDataFormat format = new ListJacksonXMLDataFormat();
// or
JacksonXMLDataFormat format = new JacksonXMLDataFormat();
format.useList();
// and you can specify the pojo class type also
format.setUnmarshalType(MyPojo.class);
```

And if you use XML DSL then you configure to use list using **useList** attribute as shown below:

```
<dataFormats>
  <jacksonxml id="jack" useList="true"/>
</dataFormats>
```

And you can specify the pojo type also

```
<dataFormats>
  <jacksonxml id="jack" useList="true" unmarshalType="com.foo.MyPojo"/>
</dataFormats>
```

53.7. USING CUSTOM JACKSON MODULES

You can use custom Jackson modules by specifying the class names of those using the `moduleClassNames` option as shown below.

```
<dataFormats>
  <jacksonxml id="jack" useList="true" unmarshalType="com.foo.MyPojo"
  moduleClassNames="com.foo.MyModule,com.foo.MyOtherModule"/>
</dataFormats>
```

When using `moduleClassNames` then the custom jackson modules are not configured, by created using default constructor and used as-is. If a custom module needs any custom configuration, then an instance of the module can be created and configured, and then use `modulesRefs` to refer to the module as shown below:

```
<bean id="myJacksonModule" class="com.foo.MyModule">
  ... // configure the module as you want
</bean>

<dataFormats>
  <jacksonxml id="jacksonxml" useList="true" unmarshalType="com.foo.MyPojo"
  moduleRefs="myJacksonModule"/>
</dataFormats>
```

Multiple modules can be specified separated by comma, such as
`moduleRefs="myJacksonModule,myOtherModule"`

53.8. ENABLING OR DISABLE FEATURES USING JACKSON

Jackson has a number of features you can enable or disable, which its `ObjectMapper` uses. For example to disable failing on unknown properties when marshalling, you can configure this using the `disableFeatures`:

```
<dataFormats>
  <jacksonxml id="jacksonxml" unmarshalType="com.foo.MyPojo"
  disableFeatures="FAIL_ON_UNKNOWN_PROPERTIES"/>
</dataFormats>
```

You can disable multiple features by separating the values using comma. The values for the features must be the name of the enums from Jackson from the following enum classes

- `com.fasterxml.jackson.databind.SerializationFeature`
- `com.fasterxml.jackson.databind.DeserializationFeature`
- `com.fasterxml.jackson.databind.MapperFeature`

To enable a feature use the `enableFeatures` options instead.

From Java code you can use the type safe methods from `camel-jackson` module:

```
JacksonDataFormat df = new JacksonDataFormat(MyPojo.class);
df.disableFeature(DeserializationFeature.FAIL_ON_UNKNOWN_PROPERTIES);
df.disableFeature(DeserializationFeature.FAIL_ON_NULL_FOR_PRIMITIVES);
```

53.9. CONVERTING MAPS TO POJO USING JACKSON

Jackson **ObjectMapper** can be used to convert maps to POJO objects. Jackson component comes with the data converter that can be used to convert `java.util.Map` instance to non-String, non-primitive and non-Number objects.

```
Map<String, Object> invoiceData = new HashMap<String, Object>();
invoiceData.put("netValue", 500);
producerTemplate.sendBody("direct:mapToInvoice", invoiceData);
...
// Later in the processor
Invoice invoice = exchange.getIn().getBody(Invoice.class);
```

If there is a single **ObjectMapper** instance available in the Camel registry, it will be used by the converter to perform the conversion. Otherwise the default mapper will be used.

53.10. FORMATTED XML MARSHALLING (PRETTY-PRINTING)

Using the **prettyPrint** option one can output a well formatted XML while marshalling:

```
<dataFormats>
  <jacksonxml id="jack" prettyPrint="true"/>
</dataFormats>
```

And in Java DSL:

```
from("direct:inPretty").marshal().jacksonxml(true);
```

Please note that there are 5 different overloaded **jacksonxml()** DSL methods which support the **prettyPrint** option in combination with other settings for **unmarshalType**, **jsonView** etc.

53.11. SPRING BOOT AUTO-CONFIGURATION

The component supports 16 options, which are listed below.

Name	Description	Default	Type
<code>camel.dataformat.jacksonxml.allow-jms-type</code>	Used for JMS users to allow the JMSType header from the JMS spec to specify a FQN classname to use to unmarshal to.	false	Boolean
<code>camel.dataformat.jacksonxml.allow-unmarshall-type</code>	If enabled then Jackson is allowed to attempt to use the CamelJacksonUnmarshalType header during the unmarshalling. This should only be enabled when desired to be used.	false	Boolean
<code>camel.dataformat.jacksonxml.collection-type</code>	Refers to a custom collection type to lookup in the registry to use. This option should rarely be used, but allows to use different collection types than java.util.Collection based as default.		String
<code>camel.dataformat.jacksonxml.content-type-header</code>	Whether the data format should set the Content-Type header with the type from the data format. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON.	true	Boolean
<code>camel.dataformat.jacksonxml.disable-features</code>	Set of features to disable on the Jackson com.fasterxml.jackson.databind.ObjectMapper. The features should be a name that matches a enum from com.fasterxml.jackson.databind.SerializationFeature, com.fasterxml.jackson.databind.DeserializationFeature, or com.fasterxml.jackson.databind.MapperFeature. Multiple features can be separated by comma.		String
<code>camel.dataformat.jacksonxml.enable-features</code>	Set of features to enable on the Jackson com.fasterxml.jackson.databind.ObjectMapper. The features should be a name that matches a enum from com.fasterxml.jackson.databind.SerializationFeature, com.fasterxml.jackson.databind.DeserializationFeature, or com.fasterxml.jackson.databind.MapperFeature. Multiple features can be separated by comma.		String
<code>camel.dataformat.jacksonxml.enable-jaxb-annotation-module</code>	Whether to enable the JAXB annotations module when using jackson. When enabled then JAXB annotations can be used by Jackson.	false	Boolean

Name	Description	Default	Type
<code>camel.dataformat.jacksonxml.enabled</code>	Whether to enable auto configuration of the jacksonxml data format. This is enabled by default.		Boolean
<code>camel.dataformat.jacksonxml.include</code>	If you want to marshal a pojo to JSON, and the pojo has some fields with null values. And you want to skip these null values, you can set this option to NON_NULL.		String
<code>camel.dataformat.jacksonxml.json-view</code>	When marshalling a POJO to JSON you might want to exclude certain fields from the JSON output. With Jackson you can use JSON views to accomplish this. This option is to refer to the class which has JsonView annotations.		String
<code>camel.dataformat.jacksonxml.module-class-names</code>	To use custom Jackson modules <code>com.fasterxml.jackson.databind.Module</code> specified as a String with FQN class names. Multiple classes can be separated by comma.		String
<code>camel.dataformat.jacksonxml.module-refs</code>	To use custom Jackson modules referred from the Camel registry. Multiple modules can be separated by comma.		String
<code>camel.dataformat.jacksonxml.pretty-print</code>	To enable pretty printing output nicely formatted. Is by default false.	false	Boolean
<code>camel.dataformat.jacksonxml.unmarshal-type</code>	Class name of the java type to use when unmarshalling.		String
<code>camel.dataformat.jacksonxml.use-list</code>	To unmarshal to a List of Map or a List of Pojo.	false	Boolean
<code>camel.dataformat.jacksonxml.xml-mapper</code>	Lookup and use the existing XmlMapper with the given id.		String

CHAPTER 54. JAXB

Since Camel 1.0

JAXB is a Data Format which uses the JAXB XML marshalling standard to unmarshal an XML payload into Java objects or to marshal Java objects into an XML payload.

54.1. DEPENDENCIES

When using **jaxb** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-jaxb-starter</artifactId>
</dependency>
```

54.2. OPTIONS

The JAXB dataformat supports 20 options, which are listed below.

Name	Default	Java Type	Description
contextPath		String	Required Package name where your JAXB classes are located.
contextPathsClassName	false	Boolean	This can be set to true to mark that the contextPath is referring to a classname and not a package name.
schema		String	To validate against an existing schema. You can use the prefix classpath:, file: or http: to specify how the resource should be resolved. You can separate multiple schema files by using the ',' character.
schemaSeverityLevel	0	Enum	Sets the schema severity level to use when validating against a schema. This level determines the minimum severity error that triggers JAXB to stop continue parsing. The default value of 0 (warning) means that any error (warning, error or fatal error) will trigger JAXB to stop. There are the following three levels: 0=warning, 1=error, 2=fatal error. Enum values: • 0 • 1 • 2
prettyPrint	false	Boolean	To enable pretty printing output nicely formatted. Is by default false.

Name	Default	Java Type	Description
objectFactory	false	Boolean	Whether to allow using ObjectFactory classes to create the POJO classes during marshalling. This only applies to POJO classes that has not been annotated with JAXB and providing jaxb.index descriptor files.
ignoreJAXBElement	false	Boolean	Whether to ignore JAXBElement elements - only needed to be set to false in very special use-cases.
mustBeJAXBElement	false	Boolean	Whether marshalling must be java objects with JAXB annotations. And if not then it fails. This option can be set to false to relax that, such as when the data is already in XML format.
filterNonXmlChars	false	Boolean	To ignore non xml characters and replace them with an empty space.
encoding		String	To overrule and use a specific encoding.
fragment	false	Boolean	To turn on marshalling XML fragment trees. By default JAXB looks for XmlRootElement annotation on given class to operate on whole XML tree. This is useful but not always - sometimes generated code does not have XmlRootElement annotation, sometimes you need unmarshall only part of tree. In that case you can use partial unmarshalling. To enable this behaviour you need set property partClass. Camel will pass this class to JAXB's unmarshaller.
partClass		String	Name of class used for fragment parsing. See more details at the fragment option.
partNamespace		String	XML namespace to use for fragment parsing. See more details at the fragment option.
namespacePrefixRef		String	When marshalling using JAXB or SOAP then the JAXB implementation will automatic assign namespace prefixes, such as ns2, ns3, ns4 etc. To control this mapping, Camel allows you to refer to a map which contains the desired mapping.
xmlStreamWriterWrapper		String	To use a custom xml stream writer.
schemaLocation		String	To define the location of the schema.
noNamespaceSchemaLocation		String	To define the location of the namespaceless schema.

Name	Default	Java Type	Description
<code>jaxbProviderProperties</code>		String	Refers to a custom <code>java.util.Map</code> to lookup in the registry containing custom JAXB provider properties to be used with the JAXB marshaller.
<code>contentTypeHeader</code>	true	Boolean	Whether the data format should set the Content-Type header with the type from the data format. For example <code>application/xml</code> for data formats marshalling to XML, or <code>application/json</code> for data formats marshalling to JSON.
<code>accessExternalSchemaProtocols</code>	false	String	Only in use if schema validation has been enabled. Restrict access to the protocols specified for external reference set by the <code>schemaLocation</code> attribute, <code>Import</code> and <code>Include</code> element. Examples of protocols are <code>file</code> , <code>http</code> , <code>jar:file</code> . <code>false</code> or <code>none</code> to deny all access to external references; a specific protocol, such as <code>file</code> , to give permission to only the protocol; the keyword <code>all</code> to grant permission to all protocols.

54.3. USING THE JAVA DSL

The following example uses a named `DataFormat` of **jaxb** which is configured with a Java package name to initialize the `JAXBContext`.

```
DataFormat jaxb = new JaxbDataFormat("com.acme.model");

from("activemq:My.Queue").
    unmarshal(jaxb).
    to("mqseries:Another.Queue");
```

You can use a named reference to a data format which can then be defined in your Registry such as via your Spring XML file.

```
from("activemq:My.Queue").
    unmarshal("myJaxbDataType").
    to("mqseries:Another.Queue");
```

54.4. USING SPRING XML

The following example shows how to configure the **JaxbDataFormat** and use it in multiple routes.

```
<beans xmlns="http://www.springframework.org/schema/beans"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://www.springframework.org/schema/beans
http://www.springframework.org/schema/beans/spring-beans.xsd
http://camel.apache.org/schema/spring http://camel.apache.org/schema/spring/camel-spring.xsd">

    <bean id="myJaxb" class="org.apache.camel.converter.jaxb.JaxbDataFormat">
```

```

    <property name="contextPath" value="org.apache.camel.example"/>
  </bean>

  <camelContext xmlns="http://camel.apache.org/schema/spring">
    <route>
      <from uri="direct:start"/>
      <marshal><custom ref="myJaxb"/></marshal>
      <to uri="direct:marshalled"/>
    </route>
    <route>
      <from uri="direct:marshalled"/>
      <unmarshal><custom ref="myJaxb"/></unmarshal>
      <to uri="mock:result"/>
    </route>
  </camelContext>

</beans>

```

54.5. MULTIPLE CONTEXT PATHS

It is possible to use this data format with more than one context path. You can specify multiple context paths using `:` as a separator, for example **com.mycompany:com.mycompany2**.

54.6. PARTIAL MARSHALLING / UNMARSHALLING

JAXB 2 supports marshalling and unmarshalling XML tree fragments. By default JAXB looks for the **@XmlRootElement** annotation on a given class to operate on whole XML tree. Sometimes the generated code does not have the **@XmlRootElement** annotation and sometimes you need to unmarshal only part of the tree.

In that case you can use partial unmarshalling. To enable this behaviour you need set property **partClass** on the **JaxbDataFormat**. Camel will pass this class to the JAXB unmarshaller. If **JaxbConstants.JAXB_PART_CLASS** is set as one of the exchange headers, its value is used to override the **partClass** property on the **JaxbDataFormat**.

For marshalling you have to add the **partNamespace** attribute with the **QName** of the destination namespace.

If **JaxbConstants.JAXB_PART_NAMESPACE** is set as one of the exchange headers, its value is used to override the **partNamespace** property on the **JaxbDataFormat**.

While setting **partNamespace** through **JaxbConstants.JAXB_PART_NAMESPACE**, please note that you need to specify its value in the format **{namespaceUri}localPart**, as per the example below.

```

.setHeader(JaxbConstants.JAXB_PART_NAMESPACE, constant(
  "{http://www.camel.apache.org/jaxb/example/address/1}address"));

```

54.7. FRAGMENT

JaxbDataFormat has a property named **fragment** which can set the **Marshaller.JAXB_FRAGMENT** property on the JAXB Marshaller. If you don't want the JAXB Marshaller to generate the XML declaration, you can set this option to be **true**. The default value of this property is **false**.

54.8. IGNORING NON-XML CHARACTERS

JaxbDataFormat supports ignoring [Non-XML Characters](#). Set the **filterNonXmlChars** property to **true**. The **JaxbDataFormat** will replace any non-XML character with a space character (" ") during message marshalling or unmarshalling. You can also set the Exchange property **Exchange.FILTER_NON_XML_CHARS**.

	JDK 1.5	JDK 1.6+
Filtering in use	StAX API and implementation	No
Filtering not in use	StAX API only	No

This feature has been tested with Woodstox 3.2.9 and Sun JDK 1.6 StAX implementation.

JaxbDataFormat now allows you to customize the **XMLStreamWriter** used to marshal the stream to XML. Using this configuration, you can add your own stream writer to completely remove, escape, or replace non-XML characters.

```
JaxbDataFormat customWriterFormat = new JaxbDataFormat("org.apache.camel.foo.bar");
customWriterFormat.setXmlStreamWriterWrapper(new TestXmlStreamWriter());
```

The following example shows using the Spring DSL and also enabling Camel's non-XML filtering:

```
<bean id="testXmlStreamWriterWrapper" class="org.apache.camel.jaxb.TestXmlStreamWriter"/>
<jaxb filterNonXmlChars="true" contextPath="org.apache.camel.foo.bar"
xmlStreamWriterWrapper="#testXmlStreamWriterWrapper" />
```

54.9. WORKING WITH THE OBJECTFACTORY

If you use XJC to create the java class from the schema, you will get an **ObjectFactory** for your JAXB context. Since the **ObjectFactory** uses the [JAXBElement](#) to hold the reference of the schema and element instance value, **JaxbDataformat** will ignore the **JAXBElement** by default and you will get the element instance value instead of the **JAXBElement** object from the unmarshaled message body.

If you want to get the **JAXBElement** object from the unmarshaled message body, you need to set the **JaxbDataFormat ignoreJAXBElement** property to be **false**.

54.10. SETTING THE ENCODING

You can set the **encoding** option on the **JaxbDataFormat** to configure the **Marshaller.JAXB_ENCODING** encoding property on the JAXB Marshaller.

You can setup which encoding to use when you declare the **JaxbDataFormat**. You can also provide the encoding in the Exchange property **Exchange.CHARSET_NAME**. This property will override the encoding set on the **JaxbDataFormat**.

54.11. CONTROLLING NAMESPACE PREFIX MAPPING

When marshalling using **JAXB** or **SOAP** then the JAXB implementation will automatic assign namespace prefixes, such as ns2, ns3, ns4 etc. To control this mapping, Camel allows you to refer to a map which contains the desired mapping.

For example, in Spring XML we can define a **Map** with the mapping. In the mapping file below, we map SOAP to use soap as a prefix. While our custom namespace <http://www.mycompany.com/foo/2> is not using any prefix.

```
<util:map id="myMap">
  <entry key="http://www.w3.org/2003/05/soap-envelope" value="soap"/>
  <!-- we don't want any prefix for our namespace -->
  <entry key="http://www.mycompany.com/foo/2" value=""/>
</util:map>
```

To use this in JAXB or SOAP data formats you refer to this map, using the **namespacePrefixRef** attribute as shown below. Then Camel will lookup in the Registry a **java.util.Map** with the id **myMap**, which was what we defined above.

```
<marshal>
  <soap version="1.2" contextPath="com.mycompany.foo" namespacePrefixRef="myMap"/>
</marshal>
```

54.12. SCHEMA VALIDATION

The **JaxbDataFormat** supports validation by marshalling and unmarshalling from / to XML. You can use the prefix **classpath:**, **file:** or **http:** to specify how the resource should be resolved. You can separate multiple schema files by using the , character.

NOTE

If the XSD schema files import/access other files, then you need to enable file protocol (or others to allow access).

Using the Java DSL, you can configure it in the following way:

```
JaxbDataFormat jaxbDataFormat = new JaxbDataFormat();
jaxbDataFormat.setContextPath(Person.class.getPackage().getName());
jaxbDataFormat.setSchema("classpath:person.xsd,classpath:address.xsd");
jaxbDataFormat.setAccessExternalSchemaProtocols("file");
```

You can do the same using the XML DSL:

```
<marshal>
  <jaxb id="jaxb" schema="classpath:person.xsd,classpath:address.xsd"
    accessExternalSchemaProtocols="file"/>
</marshal>
```

54.13. SCHEMA LOCATION

The **JaxbDataFormat** supports to specify the **SchemaLocation** when marshalling the XML.

Using the Java DSL, you can configure it in the following way:

```
JaxbDataFormat jaxbDataFormat = new JaxbDataFormat();
jaxbDataFormat.setContextPath(Person.class.getPackage().getName());
jaxbDataFormat.setSchemaLocation("schema/person.xsd");
```

You can do the same using the XML DSL:

```
<marshal>
  <jaxb id="jaxb" schemaLocation="schema/person.xsd"/>
</marshal>
```

54.14. MARSHAL DATA THAT IS ALREADY XML

The JAXB marshaller requires that the message body is JAXB compatible, e.g it is a **JAXBElement**, a java instance that has JAXB annotations, or extends **JAXBElement**. There can be situations where the message body is already in XML, e.g from a **String** type.

JaxbDataFormat has an option named **mustBeJAXBElement** which you can set to **false** to relax this check and have the JAXB marshaller only attempt marshalling on **JAXBElement** (**javax.xml.bind.JAXBIntrospector#isElement** returns **true**). In those situations the marshaller will fallback to marshal the message body as-is.

54.15. SPRING BOOT AUTO-CONFIGURATION

The component supports 21 options, which are listed below.

Name	Description	Default	Type
camel.dataformat.jaxb.access-external-schema-protocols	Only in use if schema validation has been enabled. Restrict access to the protocols specified for external reference set by the schemaLocation attribute, Import and Include element. Examples of protocols are file, http, jar:file. false or none to deny all access to external references; a specific protocol, such as file, to give permission to only the protocol; the keyword all to grant permission to all protocols.	false	String
camel.dataformat.jaxb.content-type-header	Whether the data format should set the Content-Type header with the type from the data format. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON.	true	Boolean

Name	Description	Default	Type
camel.dataformat.jaxb.context-path	Package name where your JAXB classes are located.		String
camel.dataformat.jaxb.context-path-is-class-name	This can be set to true to mark that the contextPath is referring to a classname and not a package name.	false	Boolean
camel.dataformat.jaxb.enabled	Whether to enable auto configuration of the jaxb data format. This is enabled by default.		Boolean
camel.dataformat.jaxb.encoding	To overrule and use a specific encoding.		String
camel.dataformat.jaxb.filter-non-xml-chars	To ignore non xml characheters and replace them with an empty space.	false	Boolean
camel.dataformat.jaxb.fragment	To turn on marshalling XML fragment trees. By default JAXB looks for XmlRootElement annotation on given class to operate on whole XML tree. This is useful but not always - sometimes generated code does not have XmlRootElement annotation, sometimes you need unmarshall only part of tree. In that case you can use partial unmarshalling. To enable this behaviours you need set property partClass. Camel will pass this class to JAXB's unmarshaller.	false	Boolean
camel.dataformat.jaxb.ignore-j-a-x-b-element	Whether to ignore JAXBELEMENT elements - only needed to be set to false in very special use-cases.	false	Boolean
camel.dataformat.jaxb.jaxb-provider-properties	Refers to a custom java.util.Map to lookup in the registry containing custom JAXB provider properties to be used with the JAXB marshaller.		String
camel.dataformat.jaxb.must-be-j-a-x-b-element	Whether marshalling must be java objects with JAXB annotations. And if not then it fails. This option can be set to false to relax that, such as when the data is already in XML format.	false	Boolean
camel.dataformat.jaxb.namespace-prefix-ref	When marshalling using JAXB or SOAP then the JAXB implementation will automatic assign namespace prefixes, such as ns2, ns3, ns4 etc. To control this mapping, Camel allows you to refer to a map which contains the desired mapping.		String

Name	Description	Default	Type
<code>camel.dataformat.jaxb.no-namespace-schema-location</code>	To define the location of the namespaceless schema.		String
<code>camel.dataformat.jaxb.object-factory</code>	Whether to allow using ObjectFactory classes to create the POJO classes during marshalling. This only applies to POJO classes that has not been annotated with JAXB and providing jaxb.index descriptor files.	false	Boolean
<code>camel.dataformat.jaxb.part-class</code>	Name of class used for fragment parsing. See more details at the fragment option.		String
<code>camel.dataformat.jaxb.part-namespace</code>	XML namespace to use for fragment parsing. See more details at the fragment option.		String
<code>camel.dataformat.jaxb.pretty-print</code>	To enable pretty printing output nicely formatted. Is by default false.	false	Boolean
<code>camel.dataformat.jaxb.schema</code>	To validate against an existing schema. You can use the prefix classpath:, file: or http: to specify how the resource should be resolved. You can separate multiple schema files by using the ',' character.		String
<code>camel.dataformat.jaxb.schema-location</code>	To define the location of the schema.		String
<code>camel.dataformat.jaxb.schema-severity-level</code>	Sets the schema severity level to use when validating against a schema. This level determines the minimum severity error that triggers JAXB to stop continue parsing. The default value of 0 (warning) means that any error (warning, error or fatal error) will trigger JAXB to stop. There are the following three levels: 0=warning, 1=error, 2=fatal error.	0	Integer
<code>camel.dataformat.jaxb.xml-stream-writer-wrapper</code>	To use a custom xml stream writer.		String

CHAPTER 55. JASYPT

Since Camel 2.5

Jasypt is a simplified encryption library which makes encryption and decryption easy. Camel integrates with Jasypt to allow sensitive information in [Properties](#) files to be encrypted. By dropping **camel-jasypt** on the classpath those encrypted values will automatically be decrypted on-the-fly by Camel. This ensures that human eyes can't easily spot sensitive information such as usernames and passwords.

55.1. DEPENDENCIES

When using **camel-jasypt** with Red Hat build of Camel Spring Boot, add the following Maven dependency to your **pom.xml** to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-jasypt-starter</artifactId>
</dependency>
```

55.2. TOOLING

The Jasypt component is a runnable JAR that provides a command line utility to encrypt or decrypt values. The usage documentation can be output to the console to describe the syntax and options it provides:

Apache Camel Jasypt takes the following options

```
-h or -help = Displays the help screen
-c or -command <command> = Command either encrypt or decrypt
-p or -password <password> = Password to use
-i or -input <input> = Text to encrypt or decrypt
-a or -algorithm <algorithm> = Optional algorithm to use
-rsga or -algorithm <algorithm> = Optional random salt generator algorithm to use
-riga or -algorithm <algorithm> = Optional random iv generator algorithm to use
```

A simple way of running the tool is with JBang. For example, to encrypt the value **tiger**, you can use the following parameters. Make sure to specify the version of **camel-jasypt** that you want to use.

```
$ jbang org.apache.camel:camel-jasypt:<camel version here> -c encrypt -p secret -i tiger
```

Which outputs the following result

```
Encrypted text: qaEEacuW7BUti8LcMgyjKw==
```

This means the encrypted representation **qaEEacuW7BUti8LcMgyjKw==** can be decrypted back to **tiger** if you know the master password which was **secret**.

If you run the tool again then the encrypted value will return a different result. But decrypting the value will always return the correct original value.

You can test decrypting the value by running the tooling using the following parameters:

```
$ jbang org.apache.camel:camel-jasypt:<camel version here> -c decrypt -p secret -i
qaEEacuW7BUti8LcMgyjKw==
```

Which outputs the following result:

```
Decrypted text: tiger
```

The idea is then to use those encrypted values in your [Properties](#) files. For example,

```
# Encrypted value for 'tiger'
my.secret = ENC(qaEEacuW7BUti8LcMgyjKw==)
```

55.3. PROTECTING THE MASTER PASSWORD

The master password used by Jasypt must be provided, so that it's capable of decrypting the values. However, having this master password out in the open may not be an ideal solution. Therefore, you could for example provide it as a JVM system property or as an OS environment setting. If you decide to do so then the **password** option supports prefixes that dictates this.

- **sysenv:** means to lookup the OS system environment with the given key.
- **sys:** means to lookup a JVM system property.

For example, you could provide the password before you start the application

```
$ export CAMEL_ENCRYPTION_PASSWORD=secret
```

Then start the application, such as running the start script.

When the application is up and running you can unset the environment

```
$ unset CAMEL_ENCRYPTION_PASSWORD
```

On runtimes like Spring Boot and Quarkus, you can configure a password property in the **application.properties** file as follows.

```
password=sysenv:CAMEL_ENCRYPTION_PASSWORD
```

Or if configuring **JasyptPropertiesParser** manually, you can set the password like this.

```
jasyptPropertiesParser.setPassword("sysenv:CAMEL_ENCRYPTION_PASSWORD");
```

55.4. EXAMPLE WITH JAVA DSL

On the Spring Boot and Quarkus runtimes, Camel Jasypt can be configured via configuration properties. Refer to their respective documentation pages for more information.

In Java DSL you need to configure Jasypt as a **JasyptPropertiesParser** instance and set the properties in the [Properties](#) component as shown below:

```
// create the jasypt properties parser
```

```

JasyptPropertiesParser jasypt = new JasyptPropertiesParser();
// set the master password (see above for how to do this in a secure way)
jasypt.setPassword("secret");

// create the properties' component
PropertiesComponent pc = new PropertiesComponent();
pc.setLocation("classpath:org/apache/camel/component/jasypt/secret.properties");
// and use the jasypt properties parser, so we can decrypt values
pc.setPropertiesParser(jasypt);
// end enable nested placeholder support
pc.setNestedPlaceholder(true);

// add properties component to camel context
context.setPropertiesComponent(pc);

```

It is possible to configure custom algorithms on the `JasyptPropertiesParser` like this.

```

JasyptPropertiesParser jasyptPropertiesParser = new JasyptPropertiesParser();

jasyptPropertiesParser.setAlgorithm("PBEWithHmacSHA256AndAES_256");
jasyptPropertiesParser.setRandomSaltGeneratorAlgorithm("PKCS11");
jasyptPropertiesParser.setRandomIvGeneratorAlgorithm("PKCS11");

```

The properties file **secret.properties** will contain your encrypted configuration values, such as shown below. Notice how the password value is encrypted and is surrounded like `ENC(value here)`.

```

my.secret.password=ENC(bsW9uV37gQ0QHfu7KO03Ww==)

```

55.5. EXAMPLE WITH SPRING XML

In Spring XML you need to configure the **JasyptPropertiesParser** which is shown below. Then the Camel `Properties` component is told to use **jasypt** as the properties parser, which means Jasypt has its chance to decrypt values looked up in the properties.

```

<!-- define the jasypt properties parser with the given password to be used -->
<bean id="jasypt" class="org.apache.camel.component.jasypt.JasyptPropertiesParser">
  <property name="password" value="secret"/>
</bean>

<!-- define the camel properties component -->
<bean id="properties" class="org.apache.camel.component.properties.PropertiesComponent">
  <!-- the properties file is in the classpath -->
  <property name="location"
value="classpath:org/apache/camel/component/jasypt/secret.properties"/>
  <!-- and let it leverage the jasypt parser -->
  <property name="propertiesParser" ref="jasypt"/>
  <!-- end enable nested placeholder -->
  <property name="nestedPlaceholder" value="true"/>
</bean>

```

The `Properties` component can also be inlined inside the **<camelContext>** tag which is shown below. Notice how we use the **propertiesParserRef** attribute to refer to Jasypt.

```

<!-- define the jasypt properties parser with the given password to be used -->

```

```

<bean id="jasypt" class="org.apache.camel.component.jasypt.JasyptPropertiesParser">
  <!-- password is mandatory, you can prefix it with sysenv: or sys: to indicate it should use
       an OS environment or JVM system property value, so you dont have the master password
       defined here -->
  <property name="password" value="secret"/>
</bean>

<camelContext xmlns="http://camel.apache.org/schema/spring">
  <!-- define the camel properties placeholder, and let it leverage jasypt -->
  <propertyPlaceholder id="properties"
    location="classpath:org/apache/camel/component/jasypt/myproperties.properties"
    nestedPlaceholder="true"
    propertiesParserRef="jasypt"/>

  <route>
    <from uri="direct:start"/>
    <to uri="{{cool.result}}"/>
  </route>
</camelContext>

```

55.6. SPRING BOOT AUTO-CONFIGURATION

The component supports 8 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.jasypt.algorithm</code>	The algorithm to be used for decryption.	PBEWithMD5AndDES	String
<code>camel.component.jasypt.enabled</code>	Enable the component.	false	Boolean
<code>camel.component.jasypt.iv-generator-class-name</code>	The initialization vector (IV) generator applied in decryption operations. Default: <code>org.jasypt.iv</code> .		String
<code>camel.component.jasypt.password</code>	The master password used by Jasypt for decrypting the values. This option supports prefixes which influence the master password lookup behaviour: <code>sysenv:</code> means to lookup the OS system environment with the given key. <code>sys:</code> means to lookup a JVM system property.		String
<code>camel.component.jasypt.provider-name</code>	The class name of the security provider to be used for obtaining the encryption algorithm.		String

Name	Description	Default	Type
<code>camel.component.jasypt.random-iv-generator-algorithm</code>	The algorithm for the random iv generator.	SHA1P RNG	String
<code>camel.component.jasypt.random-salt-generator-algorithm</code>	The algorithm for the salt generator.	SHA1P RNG	String
<code>camel.component.jasypt.salt-generator-class-name</code>	The salt generator applied in decryption operations. Default: <code>org.jasypt.salt.RandomSaltGenerator</code> .	<code>org.jasypt.salt.RandomSaltGenerator</code>	String

4.0// ParentAssemblies: assemblies/

CHAPTER 56. JDBC

Since Camel 1.2

Only producer is supported

The JDBC component enables you to access databases through JDBC, where SQL queries (SELECT) and operations (INSERT, UPDATE, etc) are sent in the message body. This component uses the standard JDBC API.

NOTE

Prerequisites

This component does not support transactions out of the box. For transactions, we recommend using the [Spring JDBC Component](#) instead.

56.1. DEPENDENCIES

When using **jdbc** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-jdbc-starter</artifactId>
</dependency>
```

56.2. URI FORMAT

```
jdbc:dataSourceName[?options]
```

56.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

56.3.1. Configuring Component Options

The component level is the highest level which holds general and common configurations that are inherited by the endpoints. For example, a component may have security settings, credentials for authentication, URLs for network connection.

Components have pre-configured defaults that are commonly used. hence, you need to configure only a few options on a component or none at all.

Configuring components can be done with the [Component DSL](#), in a configuration file (application.properties|yaml), or directly with Java code.

56.3.2. Configuring Endpoint Options

Endpoints have many options, which allows you to configure what you need the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from) or as a producer (to) or used for both.

Configuring endpoints is done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a *type safe* way of configuring endpoints and data formats in Java.

When configuring options is to use [Property Placeholders](#), which allows to not hard-code urls, port numbers, sensitive information, and other settings. Placeholders allows to externalize the configuration from your code, and gives more flexibility and reuse.

The following two sections lists all the options, firstly for the component followed by the endpoint.

56.4. COMPONENT OPTIONS

The JDBC component supports 4 options, which are listed below.

Name	Description	Default	Type
dataSource (producer)	To use the DataSource instance instead of looking up the data source by name from the registry.		DataSource
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
connectionStrategy (advanced)	To use a custom strategy for working with connections. Do not use a custom strategy when using the spring-jdbc component because a special Spring ConnectionStrategy is used by default to support Spring Transactions.		ConnectionStrategy

56.5. ENDPOINT OPTIONS

The JDBC endpoint is configured using URI syntax:

```
jdbc:dataSourceName
```

with the following path and query parameter:

56.5.1. Path Parameter (1 parameter)

Name	Description	Default	Type
dataSourceName (producer)	Required Name of DataSource to lookup in the Registry. If the name is dataSource or default, then Camel will attempt to lookup a default DataSource from the registry, meaning if there is a only one instance of DataSource found, then this DataSource will be used.		String

56.5.2. Query Parameters (14 parameters)

Name	Description	Default	Type
allowNamedParameters (producer)	Whether to allow using named parameters in the queries.	True	Boolean
outputClass (producer)	Specify the full package and class name to use as conversion when outputType=SelectOne or SelectList.		String
outputType (producer)	Determines the output the producer should use. Enum values: • SelectOne • SelectList • StreamList	Select List	JdbcOutputType
parameters (producer)	Optional parameters to the java.sql.Statement. For example to set maxRows, fetchSize etc.		Map
readSize (producer)	The default maximum number of rows that can be read by a polling query. The default value is 0.		int

Name	Description	Default	Type
resetAutoCommit (producer)	Camel will set the autoCommit on the JDBC connection to be false, commit the change after executed the statement and reset the autoCommit flag of the connection at the end, if the resetAutoCommit is true. If the JDBC connection doesn't support to reset the autoCommit flag, you can set the resetAutoCommit flag to be false, and Camel will not try to reset the autoCommit flag. When used with XA transactions you most likely need to set it to false so that the transaction manager is in charge of committing this tx.	True	Boolean
transacted (producer)	Whether transactions are in use.	False	Boolean
useGetBytesForBlob (producer)	To read BLOB columns as bytes instead of string data. This may be needed for certain databases such as Oracle where you must read BLOB columns as bytes.	False	Boolean
useHeadersAsParameters (producer)	Set this option to true to use the prepareStatementStrategy with named parameters. This allows to define queries with named placeholders, and use headers with the dynamic values for the query placeholders.	False	Boolean
useJDBC4ColumnNameAndLabelSemantics (producer)	Sets whether to use JDBC 4 or JDBC 3.0 or older semantic when retrieving column name. JDBC 4.0 uses columnName to get the column name where as JDBC 3.0 uses both columnName or columnLabel. Unfortunately JDBC drivers behave differently so you can use this option to work out issues around your JDBC driver if you get problem using this component. This option is default true.	True	Boolean
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	False	Boolean

Name	Description	Default	Type
beanRowMapper (advanced)	To use a custom <code>org.apache.camel.component.jdbc.BeanRowMapper</code> when using <code>outputClass</code> . The default implementation will lower case the row names and skip underscores, and dashes. For example <code>CUST_ID</code> is mapped as <code>custId</code> .		<code>BeanRowMapper</code>
connectionStrategy (advanced)	To use a custom strategy for working with connections. Do not use a custom strategy when using the <code>spring-jdbc</code> component because a special <code>Spring ConnectionStrategy</code> is used by default to support <code>Spring Transactions</code> .		<code>ConnectionStrategy</code>
prepareStatementStrategy (advanced)	Allows the plugin to use a custom <code>org.apache.camel.component.jdbc.JdbcPrepareStatementStrategy</code> to control preparation of the query and prepared statement.		<code>JdbcPrepareStatementStrategy</code>

56.6. MESSAGE HEADERS

The JBBC component supports 8 message header(s), which is/are listed below:

Name	Description	Default	Type
CamelJdbcUpdateCount (producer) Constant: <code>JDBC_UPDATE_COUNT</code>	If the query is an <code>UPDATE</code> , query the update count is returned in this <code>OUT</code> header.		<code>int</code>
CamelJdbcRowCount (producer) Constant: <code>JDBC_ROW_COUNT</code>	If the query is a <code>SELECT</code> , query the row count is returned in this <code>OUT</code> header.		<code>int</code>
CamelJdbcColumnNames (producer) Constant: <code>JDBC_COLUMN_NAMES</code>	The column names from the <code>ResultSet</code> as a <code>java.util.Set</code> type.		<code>Set</code>

Name	Description	Default	Type
CamelJdbcParameters (producer) Constant: JDBC_PARAMETERS	A java.util.Map which has the headers to be used if <code>useHeadersAsParameters</code> has been enabled.		Map
CamelRetrieveGeneratedKeys (producer) Constant: JDBC_RETRIEVE_GENERATED_KEYS	Set its value to true to retrieve generated keys.	False	Boolean
CamelGeneratedColumns (producer) Constant: JDBC_GENERATED_COLUMNS	Set it to specify the expected generated columns.		String[] or int[]
CamelGeneratedKeysRowCount (producer) Constant: JDBC_GENERATED_KEYS_ROW_COUNT	The number of rows in the header that contains generated keys.		int
CamelGeneratedKeysRows (producer) Constant: JDBC_GENERATED_KEYS_DATA	Rows that contains the generated keys.		List

56.7. RESULT

By default the result is returned in the OUT body as an **ArrayList<HashMap<String, Object>>**. The List object contains the list of rows and the **Map** objects contain each row with the **String** key as the column name. You can use the option **outputType** to control the result.

NOTE

This component fetches **ResultSetMetaData** to be able to return the column name as the key in the **Map**.

56.8. GENERATED KEYS

If you insert data using *SQL INSERT*, then the *RDBMS* may support auto generated keys. You can instruct the JDBC producer to return the generated keys in headers. To do that set the header **CamelRetrieveGeneratedKeys=true**. Then the generated keys will be provided as headers with the keys listed in the table above.

NOTE

Using generated keys does not work together with named parameters.

56.9. USING NAMED PARAMETERS

In the given route below, we want to get all the projects from the projects table. Notice the SQL query has 2 named parameters, `:?lic` and `:?min`. Camel will then lookup these parameters from the message headers. Notice in the example above we set two headers with constant value for the named parameters:

```
from("direct:projects")
  .setHeader(":?lic", constant("ASF"))
  .setHeader(":?min", constant(123))
  .setBody(simple("select * from projects where license = :?lic and id > :?min order by id"))
  .to("jdbc:myDataSource?useHeadersAsParameters=true")
```

You can also store the header values in a **java.util.Map** and store the map on the headers with the key **CamelJdbcParameters**.

56.10. SAMPLES

In the following example, we setup the DataSource that **camel-jdbc** requires. First we register our datasource in the Camel registry as **testdb**:

```
EmbeddedDatabase db = new EmbeddedDatabaseBuilder()
  .setType(EmbeddedDatabaseType.DERBY).addScript("sql/init.sql").build();

CamelContext context = ...
context.getRegistry().bind("testdb", db);
```

Then we configure a route that routes to the JDBC component, so the SQL will be executed. Note how we refer to the **testdb** datasource that was bound in the previous step:

```
from("direct:hello")
  .to("jdbc:testdb");
```

We create an endpoint, add the SQL query to the body of the IN message, and then send the exchange. The result of the query is returned in the OUT body:

```
Endpoint endpoint = context.getEndpoint("direct:hello");
Exchange exchange = endpoint.createExchange();
// then we set the SQL on the in body
exchange.getMessage().setBody("select * from customer order by ID");
// now we send the exchange to the endpoint, and receives the response from Camel
Exchange out = template.send(endpoint, exchange);
```

If you want to work on the rows one by one instead of the entire ResultSet at once you need to use the Splitter EIP such as:

```
from("direct:hello")
// here we split the data from the testdb into new messages one by one
// so the mock endpoint will receive a message per row in the table
// the StreamList option allows to stream the result of the query without creating a List of rows
// and notice we also enable streaming mode on the splitter
```

```
.to("jdbc:testdb?outputType=StreamList")
  .split(body()).streaming()
  .to("mock:result");
```

56.11. SAMPLE - POLLING THE DATABASE EVERY MINUTE

If we want to poll a database using the JDBC component, we need to combine it with a polling scheduler such as the [Timer](#) or [Quartz](#) etc. In the following example, we retrieve data from the database every 60 seconds:

```
from("timer://foo?period=60000")
  .setBody(constant("select * from customer"))
  .to("jdbc:testdb")
  .to("activemq:queue:customers");
```

56.12. SAMPLE - MOVE DATA BETWEEN DATA SOURCES

A common use case is to query for data, process it and move it to another data source (ETL operations). In the following example, we retrieve new customer records from the source table every hour, filter/transform them and move them to a destination table:

```
from("timer://MoveNewCustomersEveryHour?period=3600000")
  .setBody(constant("select * from customer where create_time > (sysdate-1/24)"))
  .to("jdbc:testdb")
  .split(body())
    .process(new MyCustomerProcessor()) //filter/transform results as needed
  .setBody(simple("insert into processed_customer values('${body[ID]}','${body[NAME]}')"))
  .to("jdbc:testdb");
```

56.13. SPRING BOOT AUTO-CONFIGURATION

The component supports 4 options, which are listed below.

Name	Description	Default	Type
camel.component.jdbc.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatically configure JDBC data sources, JMS connection factories, AWS Clients, etc.	True	Boolean
camel.component.jdbc.connection-strategy	To use a custom strategy for working with connections. Do not use a custom strategy when using the spring-jdbc component because a special Spring ConnectionStrategy is used by default to support Spring Transactions. The option is a <code>org.apache.camel.component.jdbc.ConnectionStrategy</code> type.		ConnectionStrategy

Name	Description	Default	Type
camel.component.jdbc.enabled	Whether to enable auto configuration of the jdbc component. This is enabled by default.		Boolean
camel.component.jdbc.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	False	Boolean

CHAPTER 57. JIRA

Both producer and consumer are supported

The JIRA component interacts with the JIRA API by encapsulating Atlassian's [REST Java Client for JIRA](#). It currently provides polling for new issues and new comments. It is also able to create new issues, add comments, change issues, add/remove watchers, add attachment and transition the state of an issue.

Rather than webhooks, this endpoint relies on simple polling. Reasons include:

- Concern for reliability/stability
- The types of payloads we're polling aren't typically large (plus, paging is available in the API)
- The need to support apps running somewhere not publicly accessible where a webhook would fail

Note that the JIRA API is fairly expansive. Therefore, this component could be easily expanded to provide additional interactions.

57.1. DEPENDENCIES

When using **jira** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>  
  <groupId>org.apache.camel.springboot</groupId>  
  <artifactId>camel-jira-starter</artifactId>  
</dependency>
```

57.2. URI FORMAT

```
jira://type[?options]
```

The Jira type accepts the following operations:

For consumers:

- newIssues: retrieve only new issues after the route is started
- newComments: retrieve only new comments after the route is started
- watchUpdates: retrieve only updated fields/issues based on provided jql

For producers:

- addIssue: add an issue
- addComment: add a comment on a given issue
- attach: add an attachment on a given issue
- deleteIssue: delete a given issue

- `updateIssue`: update fields of a given issue
- `transitionIssue`: transition a status of a given issue
- `watchers`: add/remove watchers of a given issue

As Jira is fully customizable, you must assure the fields IDs exists for the project and workflow, as they can change between different Jira servers.

57.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

57.3.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).
- directly in the Java code.

57.3.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

57.4. COMPONENT OPTIONS

The Jira component supports 12 options, which are listed below.

Name	Description	Default	Type
delay (common)	Time in milliseconds to elapse for the next poll.	6000	Integer
jiraUrl (common)	Required The Jira server url, example: .		String
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
configuration (advanced)	To use a shared base jira configuration.		JiraConfiguration
accessToken (security)	(OAuth only) The access token generated by the Jira server.		String
consumerKey (security)	(OAuth only) The consumer key from Jira settings.		String

Name	Description	Default	Type
password (security)	(Basic authentication only) The password to authenticate to the Jira server. Use only if username basic authentication is used.		String
privateKey (security)	(OAuth only) The private key generated by the client to encrypt the conversation to the server.		String
username (security)	(Basic authentication only) The username to authenticate to the Jira server. Use only if OAuth is not enabled on the Jira server. Do not set the username and OAuth token parameter, if they are both set, the username basic authentication takes precedence.		String
verificationCode (security)	(OAuth only) The verification code from Jira generated in the first step of the authorization process.		String

57.5. ENDPOINT OPTIONS

The Jira endpoint is configured using URI syntax:

```
jira:type
```

with the following path and query parameters:

57.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
------	-------------	---------	------

Name	Description	Default	Type
type (common)	Required Operation to perform. Consumers: NewIssues, NewComments. Producers: AddIssue, AttachFile, DeleteIssue, TransitionIssue, UpdateIssue, Watchers. See this class javadoc description for more information. Enum values: • ADDCOMMENT • ADDISSUE • ATTACH • DELETEISSUE • NEWISSUES • NEWCOMMENTS • WATCHUPDATES • UPDATEISSUE • TRANSITIONISSUE • WATCHERS • ADDISSUELINK • ADDWORKLOG • FETCHISSUE • FETCHCOMMENTS		JiraType

57.5.2. Query Parameters (16 parameters)

Name	Description	Default	Type
delay (common)	Time in milliseconds to elapse for the next poll.	6000	Integer
jiraUrl (common)	Required The Jira server url, example: .		String

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
jql (consumer)	JQL is the query language from JIRA which allows you to retrieve the data you want. For example <code>jql=project=MyProject</code> Where <code>MyProject</code> is the product key in Jira. It is important to use the <code>RAW()</code> and set the JQL inside it to prevent camel parsing it, example: <code>RAW(project in (MYP, COM) AND resolution = Unresolved)</code> .		String
maxResults (consumer)	Max number of issues to search for.	50	Integer
sendOnlyUpdatedField (consumer)	Indicator for sending only changed fields in exchange body or issue object. By default consumer sends only changed fields.	true	boolean
watchedFields (consumer)	Comma separated list of fields to watch for changes. Status,Priority are the defaults.	Status, Priority	String
exceptionHandler (consumer (advanced))	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: ● InOnly ● InOut ● InOptionalOut		ExchangePattern

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
accessToken (security)	(OAuth only) The access token generated by the Jira server.		String
consumerKey (security)	(OAuth only) The consumer key from Jira settings.		String
password (security)	(Basic authentication only) The password to authenticate to the Jira server. Use only if username basic authentication is used.		String
privateKey (security)	(OAuth only) The private key generated by the client to encrypt the conversation to the server.		String
username (security)	(Basic authentication only) The username to authenticate to the Jira server. Use only if OAuth is not enabled on the Jira server. Do not set the username and OAuth token parameter, if they are both set, the username basic authentication takes precedence.		String
verificationCode (security)	(OAuth only) The verification code from Jira generated in the first step of the authorization process.		String

57.6. CLIENT FACTORY

You can bind the **JiraRestClientFactory** with name **JiraRestClientFactory** in the registry to have it automatically set in the Jira endpoint.

57.7. AUTHENTICATION

Camel-jira supports [Basic Authentication](#) and [OAuth 3 legged authentication](#).

We recommend to use OAuth whenever possible, as it provides the best security for your users and system.

57.7.1. Basic authentication requirements:

- An username and password

57.7.2. OAuth authentication requirements:

Follow the tutorial in [Jira OAuth documentation](#) to generate the client private key, consumer key, verification code and access token.

- a private key, generated locally on your system.
- A verification code, generated by Jira server.
- The consumer key, set in the Jira server settings.
- An access token, generated by Jira server.

57.8. JQL

The JQL URI option is used by both consumer endpoints. Theoretically, items like "project key", etc. could be URI options themselves. However, by requiring the use of JQL, the consumers become much more flexible and powerful.

At the bare minimum, the consumers will require the following:

```
jira://[type]?[required options]&jql=project=[project key]
```

One important thing to note is that the newIssues consumer will automatically set the JQL as:

- append **ORDER BY key desc** to your JQL
- prepend **id > latestIssueId** to retrieve issues added after the camel route was started.

This is in order to optimize startup processing, rather than having to index every single issue in the project.

Another note is that, similarly, the newComments consumer will have to index every single issue **and** comment in the project. Therefore, for large projects, it's **vital** to optimize the JQL expression as much as possible. For example, the JIRA Toolkit Plugin includes a "Number of comments" custom field – use "Number of comments" > 0' in your query. Also try to minimize based on state (status=Open), increase the polling delay, etc. Example:

```
jira://[type]?[required options]&jql=RAW(project=[project key] AND status in (Open, \"Coding In Progress\") AND \"Number of comments\">0)
```

57.9. OPERATIONS

See a list of required headers to set when using the Jira operations. The author field for the producers is automatically set to the authenticated user in the Jira side.

If any required field is not set, then an `IllegalArgumentException` is throw.

There are operations that requires **id** for fields suchs as: issue type, priority, transition. Check the valid **id** on your jira project as they may differ on a jira installation and project workflow.

57.10. ADDISSUE

Required:

- **ProjectKey**: The project key, example: CAMEL, HHH, MYP.
- **IssueTypeId** or **IssueTypeName**: The **id** of the issue type or the name of the issue type, you can see the valid list in http://jira_server/rest/api/2/issue/createmeta?projectKeys=SAMPLE_KEY.
- **IssueSummary**: The summary of the issue.

Optional:

- **IssueAssignee**: the assignee user
- **IssuePriorityId** or **IssuePriorityName**: The priority of the issue, you can see the valid list in http://jira_server/rest/api/2/priority.
- **IssueComponents**: A list of string with the valid component names.
- **IssueWatchersAdd**: A list of strings with the usernames to add to the watcher list.
- **IssueDescription**: The description of the issue.

57.11. ADDCOMMENT

Required:

- **IssueKey**: The issue key identifier.
- body of the exchange is the description.

57.12. ATTACH

Only one file should attach per invocation.

Required:

- **IssueKey**: The issue key identifier.
- body of the exchange should be of type **File**

57.13. DELETEISSUE

Required:

- **IssueKey**: The issue key identifier.

57.14. TRANSITIONISSUE

Required:

Required:

- **IssueKey**: The issue key identifier.
- **IssueTransitionId**: The issue transition **id**.
- body of the exchange is the description.

57.15. UPDATEISSUE

- **IssueKey**: The issue key identifier.
- **IssueTypeId** or **IssueTypeName**: The **id** of the issue type or the name of the issue type, you can see the valid list in http://jira_server/rest/api/2/issue/createmeta?projectKeys=SAMPLE_KEY.
- **IssueSummary**: The summary of the issue.
- **IssueAssignee**: the assignee user
- **IssuePriorityId** or **IssuePriorityName**: The priority of the issue, you can see the valid list in http://jira_server/rest/api/2/priority.
- **IssueComponents**: A list of string with the valid component names.
- **IssueDescription**: The description of the issue.

57.16. WATCHER

- **IssueKey**: The issue key identifier.
- **IssueWatchersAdd**: A list of strings with the usernames to add to the watcher list.
- **IssueWatchersRemove**: A list of strings with the usernames to remove from the watcher list.

57.17. WATCHUPDATES (CONSUMER)

- **watchedFields** Comma separated list of fields to watch for changes i.e **Status,Priority,Assignee,Components** etc.
- **sendOnlyUpdatedField** By default only changed field is send as the body.

All messages also contain following headers that add additional info about the change:

- **issueKey**: Key of the updated issue
- **changed**: name of the updated field (i.e Status)
- **watchedIssues**: list of all issue keys that are watched in the time of update

57.18. SPRING BOOT AUTO-CONFIGURATION

The component supports 13 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.jira.access-token</code>	(OAuth only) The access token generated by the Jira server.		String
<code>camel.component.jira.autowired-enabled</code>	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
<code>camel.component.jira.bridge-error-handler</code>	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
<code>camel.component.jira.configuration</code>	To use a shared base jira configuration. The option is a <code>org.apache.camel.component.jira.JiraConfiguration</code> type.		JiraConfiguration
<code>camel.component.jira.consumer-key</code>	(OAuth only) The consumer key from Jira settings.		String
<code>camel.component.jira.delay</code>	Time in milliseconds to elapse for the next poll.	6000	Integer
<code>camel.component.jira.enabled</code>	Whether to enable auto configuration of the jira component. This is enabled by default.		Boolean
<code>camel.component.jira.jira-url</code>	The Jira server url, example: http://my_jira.com:8081/ .		String
<code>camel.component.jira.lazy-start-producer</code>	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean

Name	Description	Default	Type
camel.component.jira.password	(Basic authentication only) The password to authenticate to the Jira server. Use only if username basic authentication is used.		String
camel.component.jira.private-key	(OAuth only) The private key generated by the client to encrypt the conversation to the server.		String
camel.component.jira.username	(Basic authentication only) The username to authenticate to the Jira server. Use only if OAuth is not enabled on the Jira server. Do not set the username and OAuth token parameter, if they are both set, the username basic authentication takes precedence.		String
camel.component.jira.verification-code	(OAuth only) The verification code from Jira generated in the first step of the authorization process.		String

CHAPTER 58. JMS

Both producer and consumer are supported

This component allows messages to be sent to (or consumed from) a [JMS](#) Queue or Topic. It uses Spring's JMS support for declarative transactions, including Spring's **JmsTemplate** for sending and a **MessageListenerContainer** for consuming.

58.1. DEPENDENCIES

When using **jms** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-jms-starter</artifactId>
</dependency>
```

NOTE

Using ActiveMQ

If you are using [Apache ActiveMQ](#), you should prefer the ActiveMQ component as it has been optimized for ActiveMQ. All of the options and samples on this page are also valid for the ActiveMQ component.

NOTE

Transacted and caching

See section **Transactions and Cache Levels** below if you are using transactions with [JMS](#) as it can impact performance.

NOTE

Request/Reply over JMS

Make sure to read the section *Request/reply over JMS* further below on this page for important notes about request/reply, as Camel offers a number of options to configure for performance, and clustered environments.

58.2. URI FORMAT

```
jms:[queue:]topic:destinationName[?options]
```

Where **destinationName** is a JMS queue or topic name. By default, the **destinationName** is interpreted as a queue name. For example, to connect to the queue, **FOO.BAR** use:

```
jms:FOO.BAR
```

You can include the optional **queue:** prefix, if you prefer:

```
jms:queue:FOO.BAR
```

To connect to a topic, you *must* include the **topic:** prefix. For example, to connect to the topic, **Stocks.Prices**, use:

```
jms:topic:Stocks.Prices
```

You append query options to the URI by using the following format,

?option=value&option=value&...

58.2.1. Using ActiveMQ

The JMS component reuses Spring 2's **JmsTemplate** for sending messages. This is not ideal for use in a non-J2EE container and typically requires some caching in the JMS provider to avoid [poor performance](#).

If you intend to use [Apache ActiveMQ](#) as your message broker, the recommendation is that you do one of the following:

- Use the ActiveMQ component, which is already optimized to use ActiveMQ efficiently
- Use the **PoolingConnectionFactory** in ActiveMQ.

58.2.2. Transactions and Cache Levels

If you are consuming messages and using transactions (**transacted=true**) then the default settings for cache level can impact performance.

If you are using XA transactions then you cannot cache as it can cause the XA transaction to not work properly.

If you are **not** using XA, then you should consider caching as it speeds up performance, such as setting **cacheLevelName=CACHE_CONSUMER**.

The default setting for **cacheLevelName** is **CACHE_AUTO**. This default auto detects the mode and sets the cache level accordingly to:

- **CACHE_CONSUMER** if **transacted=false**
- **CACHE_NONE** if **transacted=true**

So you can say the default setting is conservative. Consider using **cacheLevelName=CACHE_CONSUMER** if you are using non-XA transactions.

58.2.3. Durable Subscriptions with JMS 1.1

If you wish to use durable topic subscriptions, you need to specify both **clientId** and **durableSubscriptionName**. The value of the **clientId** must be unique and can only be used by a single JMS connection instance in your entire network.

NOTE

If you are using the [Apache ActiveMQ Classic](#), you may prefer to use a feature called Virtual Topic. This should remove the necessity of having a unique **clientId**. You can consult the specific documentation for [Artemis](#) or for [ActiveMQ Classic](#) for details about how to leverage this feature. You can find more details about durable messaging for ActiveMQ Classic [here](#).

58.2.3.1. Durable Subscriptions with JMS 2.0

If you wish to use durable topic subscriptions, you need to specify the **durableSubscriptionName**.

58.2.4. Message Header Mapping

When using message headers, the JMS specification states that header names must be valid Java identifiers. So try to name your headers to be valid Java identifiers. One benefit of doing this is that you can then use your headers inside a JMS Selector (whose SQL92 syntax mandates Java identifier syntax for headers).

A simple strategy for mapping header names is used by default. The strategy is to replace any dots and hyphens in the header name as shown below and to reverse the replacement when the header name is restored from a JMS message sent over the wire. What does this mean? No more losing method names to invoke on a bean component, no more losing the filename header for the File Component, and so on.

The current header name strategy for accepting header names in Camel is as follows:

- Dots are replaced by ``DOT`` and the replacement is reversed when Camel consume the message
- Hyphen is replaced by ``HYPHEN`` and the replacement is reversed when Camel consumes the message

You can configure many different properties on the JMS endpoint, which map to properties on the **JMSConfiguration** object.

NOTE

Mapping to Spring JMS

Many of these properties map to properties on Spring JMS, which Camel uses for sending and receiving messages. So you can get more information about these properties by consulting the relevant Spring documentation.

58.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

58.3.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a

few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).
- directly in the Java code.

58.3.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

58.4. COMPONENT OPTIONS

The JMS component supports 98 options, which are listed below.

Name	Description	Default	Type
clientId (common)	Sets the JMS client ID to use. Note that this value, if specified, must be unique and can only be used by a single JMS connection instance. The clientId option is compulsory with JMS 1.1 durable topic subscriptions, because the client ID is used to control which client messages have to be stored for. With JMS 2.0 clients, clientId may be omitted, which creates a 'global' subscription. If using Apache ActiveMQ you may prefer to use Virtual Topics instead.		String

Name	Description	Default	Type
connectionFactory (common)	The connection factory to be use. A connection factory must be configured either on the component or endpoint.		ConnectionFactory
disableReplyTo (common)	Specifies whether Camel ignores the JMSReplyTo header in messages. If true, Camel does not send a reply back to the destination specified in the JMSReplyTo header. You can use this option if you want Camel to consume from a route and you do not want Camel to automatically send back a reply message because another component in your code handles the reply message. You can also use this option if you want to use Camel as a proxy between different message brokers and you want to route message from one system to another.	false	boolean
durableSubscriptionName (common)	The durable subscriber name for specifying durable topic subscriptions. The clientId option must be configured for a JMS 1.1 durable subscription, and may be configured for JMS 2.0, to create a private durable subscription.		String
jmsMessageType (common)	Allows you to force the use of a specific javax.jms.Message implementation for sending JMS messages. Possible values are: Bytes, Map, Object, Stream, Text. By default, Camel would determine which JMS message type to use from the In body type. This option allows you to specify it. Enum values: • Bytes • Map • Object • Stream • Text		JmsMessageType
replyTo (common)	Provides an explicit ReplyTo destination (overrides any incoming value of Message.getJMSReplyTo() in consumer).		String

Name	Description	Default	Type
testConnectionOnStartup (common)	Specifies whether to test the connection on startup. This ensures that when Camel starts that all the JMS consumers have a valid connection to the JMS broker. If a connection cannot be granted then Camel throws an exception on startup. This ensures that Camel is not started with failed connections. The JMS producers is tested as well.	false	boolean
acknowledgmentModeName (consumer)	The JMS acknowledgement name, which is one of: SESSION_TRANSACTED, CLIENT_ACKNOWLEDGE, AUTO_ACKNOWLEDGE, DUPS_OK_ACKNOWLEDGE. Enum values: • SESSION_TRANSACTED • CLIENT_ACKNOWLEDGE • AUTO_ACKNOWLEDGE • DUPS_OK_ACKNOWLEDGE	AUTO_ACKNOWLEDGE	String
artemisConsumerPriority (consumer)	Consumer priorities allow you to ensure that high priority consumers receive messages while they are active. Normally, active consumers connected to a queue receive messages from it in a round-robin fashion. When consumer priorities are in use, messages are delivered round-robin if multiple active consumers exist with the same high priority. Messages will only going to lower priority consumers when the high priority consumers do not have credit available to consume the message, or those high priority consumers have declined to accept the message (for instance because it does not meet the criteria of any selectors associated with the consumer).		int

Name	Description	Default	Type
asyncConsumer (consumer)	Whether the JmsConsumer processes the Exchange asynchronously. If enabled then the JmsConsumer may pickup the next message from the JMS queue, while the previous message is being processed asynchronously (by the Asynchronous Routing Engine). This means that messages may be processed not 100% strictly in order. If disabled (as default) then the Exchange is fully processed before the JmsConsumer picks up the next message from the JMS queue. Note if transacted has been enabled, then asyncConsumer=true does not run asynchronously, as transaction must be executed synchronously (Camel 3.0 may support async transactions).	false	boolean
autoStartup (consumer)	Specifies whether the consumer container should auto-startup.	true	boolean
cacheLevel (consumer)	Sets the cache level by ID for the underlying JMS resources. See cacheLevelName option for more details.		int
cacheLevelName (consumer)	Sets the cache level by name for the underlying JMS resources. Possible values are: CACHE_AUTO, CACHE_CONNECTION, CACHE_CONSUMER, CACHE_NONE, and CACHE_SESSION. The default setting is CACHE_AUTO. See the Spring documentation and Transactions Cache Levels for more information. Enum values: ● CACHE_AUTO ● CACHE_CONNECTION ● CACHE_CONSUMER ● CACHE_NONE ● CACHE_SESSION	CACHE_AUTO	String
concurrentConsumers (consumer)	Specifies the default number of concurrent consumers when consuming from JMS (not for request/reply over JMS). See also the maxMessagesPerTask option to control dynamic scaling up/down of threads. When doing request/reply over JMS then the option replyToConcurrentConsumers is used to control number of concurrent consumers on the reply message listener.	1	int

Name	Description	Default	Type
maxConcurrentConsumers (consumer)	Specifies the maximum number of concurrent consumers when consuming from JMS (not for request/reply over JMS). See also the <code>maxMessagesPerTask</code> option to control dynamic scaling up/down of threads. When doing request/reply over JMS then the option <code>replyToMaxConcurrentConsumers</code> is used to control number of concurrent consumers on the reply message listener.		int
replyToDeliveryPersistent (consumer)	Specifies whether to use persistent delivery by default for replies.	true	boolean
selector (consumer)	Sets the JMS selector to use.		String
subscriptionDurable (consumer)	Set whether to make the subscription durable. The durable subscription name to be used can be specified through the <code>subscriptionName</code> property. Default is false. Set this to true to register a durable subscription, typically in combination with a <code>subscriptionName</code> value (unless your message listener class name is good enough as subscription name). Only makes sense when listening to a topic (pub-sub domain), therefore this method switches the <code>pubSubDomain</code> flag as well.	false	boolean
subscriptionName (consumer)	Set the name of a subscription to create. To be applied in case of a topic (pub-sub domain) with a shared or durable subscription. The subscription name needs to be unique within this client's JMS client id, if the client ID is configured. Default is the class name of the specified message listener. Note: Only 1 concurrent consumer (which is the default of this message listener container) is allowed for each subscription, except for a shared subscription (which requires JMS 2.0).		String

Name	Description	Default	Type
subscriptionShared (consumer)	Set whether to make the subscription shared. The shared subscription name to be used can be specified through the <code>subscriptionName</code> property. Default is false. Set this to true to register a shared subscription, typically in combination with a <code>subscriptionName</code> value (unless your message listener class name is good enough as subscription name). Note that shared subscriptions may also be durable, so this flag can (and often will) be combined with <code>subscriptionDurable</code> as well. Only makes sense when listening to a topic (pub-sub domain), therefore this method switches the <code>pubSubDomain</code> flag as well. Requires a JMS 2.0 compatible message broker.	false	boolean
acceptMessagesWhileStopping (consumer (advanced))	Specifies whether the consumer accept messages while it is stopping. You may consider enabling this option, if you start and stop JMS routes at runtime, while there are still messages enqueued on the queue. If this option is false, and you stop the JMS route, then messages may be rejected, and the JMS broker would have to attempt redeliveries, which yet again may be rejected, and eventually the message may be moved at a dead letter queue on the JMS broker. To avoid this its recommended to enable this option.	false	boolean
allowReplyManagerQuickStop (consumer (advanced))	Whether the <code>DefaultMessageListenerContainer</code> used in the reply managers for request/reply messaging allow the <code>DefaultMessageListenerContainer.runningAllowed</code> flag to quick stop in case <code>JmsConfiguration#isAcceptMessagesWhileStopping</code> is enabled, and <code>org.apache.camel.CamelContext</code> is currently being stopped. This quick stop ability is enabled by default in the regular JMS consumers but to enable for reply managers you must enable this flag.	false	boolean

Name	Description	Default	Type
consumerType (consumer (advanced))	The consumer type to use, which can be one of: Simple, Default, or Custom. The consumer type determines which Spring JMS listener to use. Default will use <code>org.springframework.jms.listener.DefaultMessageListenerContainer</code>, Simple will use <code>org.springframework.jms.listener.SimpleMessageListenerContainer</code>. When Custom is specified, the <code>MessageListenerContainerFactory</code> defined by the <code>messageListenerContainerFactory</code> option will determine what <code>org.springframework.jms.listener.AbstractMessageListenerContainer</code> to use. Enum values: • Simple • Default • Custom	Default	ConsumerType
defaultTaskExecutorType (consumer (advanced))	Specifies what default <code>TaskExecutor</code> type to use in the <code>DefaultMessageListenerContainer</code>, for both consumer endpoints and the <code>ReplyTo</code> consumer of producer endpoints. Possible values: <code>SimpleAsync</code> (uses Spring's <code>SimpleAsyncTaskExecutor</code>) or <code>ThreadPool</code> (uses Spring's <code>ThreadPoolTaskExecutor</code> with optimal values - cached threadpool-like). If not set, it defaults to the previous behaviour, which uses a cached thread pool for consumer endpoints and <code>SimpleAsync</code> for reply consumers. The use of <code>ThreadPool</code> is recommended to reduce thread trash in elastic configurations with dynamically increasing and decreasing concurrent consumers. Enum values: • <code>ThreadPool</code> • <code>SimpleAsync</code>		DefaultTaskExecutorType
eagerLoadingOfProperties (consumer (advanced))	Enables eager loading of JMS properties and payload as soon as a message is loaded which generally is inefficient as the JMS properties may not be required but sometimes can catch early any issues with the underlying JMS provider and the use of JMS properties. See also the option <code>eagerPoisonBody</code>.	false	boolean

Name	Description	Default	Type
eagerPoisonBody (consumer (advanced))	If eagerLoadingOfProperties is enabled and the JMS message payload (JMS body or JMS properties) is poison (cannot be read/mapped), then set this text as the message body instead so the message can be processed (the cause of the poison are already stored as exception on the Exchange). This can be turned off by setting eagerPoisonBody=false. See also the option eagerLoadingOfProperties.	Poison JMS message due to <code>{exception.message}</code>	String
exposeListenerSession (consumer (advanced))	Specifies whether the listener session should be exposed when consuming messages.	false	boolean
replyToSameDestinationAllowed (consumer (advanced))	Whether a JMS consumer is allowed to send a reply message to the same destination that the consumer is using to consume from. This prevents an endless loop by consuming and sending back the same message to itself.	false	boolean
taskExecutor (consumer (advanced))	Allows you to specify a custom task executor for consuming messages.		TaskExecutor
deliveryDelay (producer)	Sets delivery delay to use for send calls for JMS. This option requires JMS 2.0 compliant broker.	-1	long
deliveryMode (producer)	Specifies the delivery mode to be used. Possible values are those defined by <code>javax.jms.DeliveryMode</code> . <code>NON_PERSISTENT</code> = 1 and <code>PERSISTENT</code> = 2. Enum values: • 1 • 2		Integer
deliveryPersistent (producer)	Specifies whether persistent delivery is used by default.	true	boolean

Name	Description	Default	Type
explicitQosEnabled (producer)	Set if the deliveryMode, priority or timeToLive qualities of service should be used when sending messages. This option is based on Spring's JmsTemplate. The deliveryMode, priority and timeToLive options are applied to the current endpoint. This contrasts with the preserveMessageQos option, which operates at message granularity, reading QoS properties exclusively from the Camel In message headers.	false	Boolean
formatDateHeadersToIso8601 (producer)	Sets whether JMS date properties should be formatted according to the ISO 8601 standard.	false	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
preserveMessageQos (producer)	Set to true, if you want to send message using the QoS settings specified on the message, instead of the QoS settings on the JMS endpoint. The following three headers are considered JMSPriority, JMSDeliveryMode, and JMSExpiration. You can provide all or only some of them. If not provided, Camel will fall back to use the values from the endpoint instead. So, when using this option, the headers override the values from the endpoint. The explicitQosEnabled option, by contrast, will only use options set on the endpoint, and not values from the message header.	false	boolean

Name	Description	Default	Type
priority (producer)	Values greater than 1 specify the message priority when sending (where 1 is the lowest priority and 9 is the highest). The <code>explicitQosEnabled</code> option must also be enabled in order for this option to have any effect. Enum values: • 1 • 2 • 3 • 4 • 5 • 6 • 7 • 8 • 9	4	int
replyToConcurrentConsumers (producer)	Specifies the default number of concurrent consumers when doing request/reply over JMS. See also the <code>maxMessagesPerTask</code> option to control dynamic scaling up/down of threads.	1	int
replyToMaxConcurrentConsumers (producer)	Specifies the maximum number of concurrent consumers when using request/reply over JMS. See also the <code>maxMessagesPerTask</code> option to control dynamic scaling up/down of threads.		int
replyToOnTimeoutMaxConcurrentConsumers (producer)	Specifies the maximum number of concurrent consumers for continue routing when timeout occurred when using request/reply over JMS.	1	int
replyToOverride (producer)	Provides an explicit <code>ReplyTo</code> destination in the JMS message, which overrides the setting of <code>replyTo</code> . It is useful if you want to forward the message to a remote Queue and receive the reply message from the <code>ReplyTo</code> destination.		String

Name	Description	Default	Type
replyToType (producer)	Allows for explicitly specifying which kind of strategy to use for replyTo queues when doing request/reply over JMS. Possible values are: Temporary, Shared, or Exclusive. By default Camel will use temporary queues. However if replyTo has been configured, then Shared is used by default. This option allows you to use exclusive queues instead of shared ones. See Camel JMS documentation for more details, and especially the notes about the implications if running in a clustered environment, and the fact that Shared reply queues has lower performance than its alternatives Temporary and Exclusive. Enum values: • Temporary • Shared • Exclusive		ReplyToType
requestTimeout (producer)	The timeout for waiting for a reply when using the InOut Exchange Pattern (in milliseconds). The default is 20 seconds. You can include the header CamelJmsRequestTimeout to override this endpoint configured timeout value, and thus have per message individual timeout values. See also the requestTimeoutCheckerInterval option.	20000	long
timeToLive (producer)	When sending messages, specifies the time-to-live of the message (in milliseconds).	-1	long
allowAdditionalHeaders (producer (advanced))	This option is used to allow additional headers which may have values that are invalid according to JMS specification. For example some message systems such as WMQ do this with header names using prefix JMS_IBM_MQMD_ containing values with byte array or other invalid types. You can specify multiple header names separated by comma, and use as suffix for wildcard matching.		String
allowNullBody (producer (advanced))	Whether to allow sending messages with no body. If this option is false and the message body is null, then an JMSEException is thrown.	true	boolean

Name	Description	Default	Type
alwaysCopyMessage (producer (advanced))	If true, Camel will always make a JMS message copy of the message when it is passed to the producer for sending. Copying the message is needed in some situations, such as when a <code>replyToDestinationSelectorName</code> is set (incidentally, Camel will set the <code>alwaysCopyMessage</code> option to true, if a <code>replyToDestinationSelectorName</code> is set).	false	boolean
correlationProperty (producer (advanced))	When using InOut exchange pattern use this JMS property instead of <code>JMSCorrelationID</code> JMS property to correlate messages. If set messages will be correlated solely on the value of this property <code>JMSCorrelationID</code> property will be ignored and not set by Camel.		String
disableTimeToLive (producer (advanced))	Use this option to force disabling time to live. For example when you do request/reply over JMS, then Camel will by default use the <code>requestTimeout</code> value as time to live on the message being sent. The problem is that the sender and receiver systems have to have their clocks synchronized, so they are in sync. This is not always so easy to archive. So you can use <code>disableTimeToLive=true</code> to not set a time to live value on the sent message. Then the message will not expire on the receiver system. See below in section About time to live for more details.	false	boolean
forceSendOriginalMessage (producer (advanced))	When using <code>mapJmsMessage=false</code> Camel will create a new JMS message to send to a new JMS destination if you touch the headers (get or set) during the route. Set this option to true to force Camel to send the original JMS message that was received.	false	boolean
includeSentJMSMessageID (producer (advanced))	Only applicable when sending to JMS destination using InOnly (eg fire and forget). Enabling this option will enrich the Camel Exchange with the actual <code>JMSMessageID</code> that was used by the JMS client when the message was sent to the JMS destination.	false	boolean

Name	Description	Default	Type
replyToCacheLevelName (producer (advanced))	Sets the cache level by name for the reply consumer when doing request/reply over JMS. This option only applies when using fixed reply queues (not temporary). Camel will by default use: <code>CACHE_CONSUMER</code> for exclusive or shared w/ <code>replyToSelectorName</code>. And <code>CACHE_SESSION</code> for shared without <code>replyToSelectorName</code>. Some JMS brokers such as IBM WebSphere may require to set the <code>replyToCacheLevelName=CACHE_NONE</code> to work. Note: If using temporary queues then <code>CACHE_NONE</code> is not allowed, and you must use a higher value such as <code>CACHE_CONSUMER</code> or <code>CACHE_SESSION</code>. Enum values: ● <code>CACHE_AUTO</code> ● <code>CACHE_CONNECTION</code> ● <code>CACHE_CONSUMER</code> ● <code>CACHE_NONE</code> ● <code>CACHE_SESSION</code>		String
replyToSelectorName (producer (advanced))	Sets the JMS Selector using the fixed name to be used so you can filter out your own replies from the others when using a shared queue (that is, if you are not using a temporary reply queue).		String
streamMessageTypeEnabled (producer (advanced))	Sets whether <code>StreamMessage</code> type is enabled or not. Message payloads of streaming kind such as files, <code>InputStream</code> , etc will either be sent as <code>BytesMessage</code> or <code>StreamMessage</code> . This option controls which kind will be used. By default <code>BytesMessage</code> is used which enforces the entire message payload to be read into memory. By enabling this option the message payload is read into memory in chunks and each chunk is then written to the <code>StreamMessage</code> until no more data.	false	boolean
allowAutoWiredConnectionFactory (advanced)	Whether to auto-discover <code>ConnectionFactory</code> from the registry, if no connection factory has been configured. If only one instance of <code>ConnectionFactory</code> is found then it will be used. This is enabled by default.	true	boolean

Name	Description	Default	Type
allowAutoWiredDestinationResolver (advanced)	Whether to auto-discover DestinationResolver from the registry, if no destination resolver has been configured. If only one instance of DestinationResolver is found then it will be used. This is enabled by default.	true	boolean
allowSerializedHeaders (advanced)	Controls whether or not to include serialized headers. Applies only when transferExchange is true. This requires that the objects are serializable. Camel will exclude any non-serializable objects and log it at WARN level.	false	boolean
artemisStreamingEnabled (advanced)	Whether optimizing for Apache Artemis streaming mode. This can reduce memory overhead when using Artemis with JMS StreamMessage types. This option must only be enabled if Apache Artemis is being used.	false	boolean
asyncStartListener (advanced)	Whether to startup the JmsConsumer message listener asynchronously, when starting a route. For example if a JmsConsumer cannot get a connection to a remote JMS broker, then it may block while retrying and/or failover. This will cause Camel to block while starting routes. By setting this option to true, you will let routes startup, while the JmsConsumer connects to the JMS broker using a dedicated thread in asynchronous mode. If this option is used, then beware that if the connection could not be established, then an exception is logged at WARN level, and the consumer will not be able to receive messages; You can then restart the route to retry.	false	boolean
asyncStopListener (advanced)	Whether to stop the JmsConsumer message listener asynchronously, when stopping a route.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
configuration (advanced)	To use a shared JMS configuration.		JmsConfiguration

Name	Description	Default	Type
destinationResolver (advanced)	A pluggable <code>org.springframework.jms.support.destination.DestinationResolver</code> that allows you to use your own resolver (for example, to lookup the real destination in a JNDI registry).		<code>DestinationResolver</code>
errorHandler (advanced)	Specifies a <code>org.springframework.util.ErrorHandler</code> to be invoked in case of any uncaught exceptions thrown while processing a <code>Message</code> . By default these exceptions will be logged at the <code>WARN</code> level, if no <code>errorHandler</code> has been configured. You can configure logging level and whether stack traces should be logged using <code>errorHandlerLoggingLevel</code> and <code>errorHandlerLogStackTrace</code> options. This makes it much easier to configure, than having to code a custom <code>ErrorHandler</code> .		<code>ErrorHandler</code>
exceptionListener (advanced)	Specifies the JMS Exception Listener that is to be notified of any underlying JMS exceptions.		<code>ExceptionListener</code>
idleConsumerLimit (advanced)	Specify the limit for the number of consumers that are allowed to be idle at any given time.	1	int
idleTaskExecutionLimit (advanced)	Specifies the limit for idle executions of a receive task, not having received any message within its execution. If this limit is reached, the task will shut down and leave receiving to other executing tasks (in the case of dynamic scheduling; see the <code>maxConcurrentConsumers</code> setting). There is additional doc available from Spring.	1	int
includeAllJMSXProperties (advanced)	Whether to include all <code>JMSXxxx</code> properties when mapping from JMS to Camel Message. Setting this to true will include properties such as <code>JMSXAppID</code> , and <code>JMSXUserID</code> etc. Note: If you are using a custom <code>headerFilterStrategy</code> then this option does not apply.	false	boolean

Name	Description	Default	Type
jmsKeyFormatStrategy (advanced)	Pluggable strategy for encoding and decoding JMS keys so they can be compliant with the JMS specification. Camel provides two implementations out of the box: default and passthrough. The default strategy will safely marshal dots and hyphens (. and -). The passthrough strategy leaves the key as is. Can be used for JMS brokers which do not care whether JMS header keys contain illegal characters. You can provide your own implementation of the <code>org.apache.camel.component.jms.JmsKeyFormatStrategy</code> and refer to it using the <code>#</code> notation. Enum values: • default • passthrough		JmsKeyFormatStrategy
mapJmsMessage (advanced)	Specifies whether Camel should auto map the received JMS message to a suited payload type, such as <code>javax.jms.TextMessage</code> to a <code>String</code> etc.	true	boolean
maxMessagesPerTask (advanced)	The number of messages per task. -1 is unlimited. If you use a range for concurrent consumers (eg min max), then this option can be used to set a value to eg 100 to control how fast the consumers will shrink when less work is required.	-1	int
messageConverter (advanced)	To use a custom Spring <code>org.springframework.jms.support.converter.MessageConverter</code> so you can be in control how to map to/from a <code>javax.jms.Message</code> .		MessageConverter
messageCreatedStrategy (advanced)	To use the given <code>MessageCreatedStrategy</code> which are invoked when Camel creates new instances of <code>javax.jms.Message</code> objects when Camel is sending a JMS message.		MessageCreatedStrategy
messageIdEnabled (advanced)	When sending, specifies whether message IDs should be added. This is just an hint to the JMS broker. If the JMS provider accepts this hint, these messages must have the message ID set to null; if the provider ignores the hint, the message ID must be set to its normal unique value.	true	boolean

Name	Description	Default	Type
messageListenerContainerFactory (advanced)	Registry ID of the MessageListenerContainerFactory used to determine what <code>org.springframework.jms.listener.AbstractMessageListenerContainer</code> to use to consume messages. Setting this will automatically set <code>consumerType</code> to Custom.		MessageListenerContainerFactory
messageTimestampEnabled (advanced)	Specifies whether timestamps should be enabled by default on sending messages. This is just an hint to the JMS broker. If the JMS provider accepts this hint, these messages must have the timestamp set to zero; if the provider ignores the hint the timestamp must be set to its normal value.	true	boolean
pubSubNoLocal (advanced)	Specifies whether to inhibit the delivery of messages published by its own connection.	false	boolean
queueBrowseStrategy (advanced)	To use a custom QueueBrowseStrategy when browsing queues.		QueueBrowseStrategy
receiveTimeout (advanced)	The timeout for receiving messages (in milliseconds).	1000	long
recoveryInterval (advanced)	Specifies the interval between recovery attempts, i.e. when a connection is being refreshed, in milliseconds. The default is 5000 ms, that is, 5 seconds.	5000	long
requestTimeoutCheckerInterval (advanced)	Configures how often Camel should check for timed out Exchanges when doing request/reply over JMS. By default Camel checks once per second. But if you must react faster when a timeout occurs, then you can lower this interval, to check more frequently. The timeout is determined by the option <code>requestTimeout</code> .	1000	long
synchronous (advanced)	Sets whether synchronous processing should be strictly used.	false	boolean

Name	Description	Default	Type
transferException (advanced)	If enabled and you are using Request Reply messaging (InOut) and an Exchange failed on the consumer side, then the caused Exception will be send back in response as a javax.jms.ObjectMessage. If the client is Camel, the returned Exception is rethrown. This allows you to use Camel JMS as a bridge in your routing - for example, using persistent queues to enable robust routing. Notice that if you also have transferExchange enabled, this option takes precedence. The caught exception is required to be serializable. The original Exception on the consumer side can be wrapped in an outer exception such as org.apache.camel.RuntimeCamelException when returned to the producer. Use this with caution as the data is using Java Object serialization and requires the receiver to be able to deserialize the data at Class level, which forces a strong coupling between the producers and consumer!.	false	boolean
transferExchange (advanced)	You can transfer the exchange over the wire instead of just the body and headers. The following fields are transferred: In body, Out body, Fault body, In headers, Out headers, Fault headers, exchange properties, exchange exception. This requires that the objects are serializable. Camel will exclude any non-serializable objects and log it at WARN level. You must enable this option on both the producer and consumer side, so Camel knows the payloads is an Exchange and not a regular payload. Use this with caution as the data is using Java Object serialization and requires the receiver to be able to deserialize the data at Class level, which forces a strong coupling between the producers and consumers having to use compatible Camel versions!.	false	boolean
useMessageIDAsCorrelationID (advanced)	Specifies whether JMSMessageID should always be used as JMSCorrelationID for InOut messages.	false	boolean
waitForProvisionCorrelationToBeUpdatedCounter (advanced)	Number of times to wait for provisional correlation id to be updated to the actual correlation id when doing request/reply over JMS and when the option useMessageIDAsCorrelationID is enabled.	50	int

Name	Description	Default	Type
waitForProvisionCorrelationToBeUpdatedThreadSleepingTime (advanced)	Interval in millis to sleep each time while waiting for provisional correlation id to be updated.	100	long
headerFilterStrategy (filter)	To use a custom <code>org.apache.camel.spi.HeaderFilterStrategy</code> to filter header to and from Camel message.		HeaderFilterStrategy
errorHandlerLoggingLevel (logging)	Allows to configure the default errorHandler logging level for logging uncaught exceptions. Enum values: • TRACE • DEBUG • INFO • WARN • ERROR • OFF	WARN	LoggingLevel
errorHandlerLogStackTrace (logging)	Allows to control whether stacktraces should be logged or not, by the default errorHandler.	true	boolean
password (security)	Password to use with the ConnectionFactory. You can also configure username/password directly on the ConnectionFactory.		String
username (security)	Username to use with the ConnectionFactory. You can also configure username/password directly on the ConnectionFactory.		String
transacted (transaction)	Specifies whether to use transacted mode.	false	boolean

Name	Description	Default	Type
transactedInOut (transaction)	Specifies whether InOut operations (request reply) default to using transacted mode. If this flag is set to true, then Spring JmsTemplate will have sessionTransacted set to true, and the acknowledgeMode as transacted on the JmsTemplate used for InOut operations. Note from Spring JMS: that within a JTA transaction, the parameters passed to createQueue, createTopic methods are not taken into account. Depending on the Java EE transaction context, the container makes its own decisions on these values. Analogously, these parameters are not taken into account within a locally managed transaction either, since Spring JMS operates on an existing JMS Session in this case. Setting this flag to true will use a short local JMS transaction when running outside of a managed transaction, and a synchronized local JMS transaction in case of a managed transaction (other than an XA transaction) being present. This has the effect of a local JMS transaction being managed alongside the main transaction (which might be a native JDBC transaction), with the JMS transaction committing right after the main transaction.	false	boolean
lazyCreateTransactionManager (transaction advanced))	If true, Camel will create a JmsTransactionManager, if there is no transactionManager injected when option transacted=true.	true	boolean
transactionManager (transaction advanced))	The Spring transaction manager to use.		PlatformTransactionManager
transactionName (transaction advanced))	The name of the transaction to use.		String
transactionTimeout (transaction advanced))	The timeout value of the transaction (in seconds), if using transacted mode.	-1	int

58.5. ENDPOINT OPTIONS

The JMS endpoint is configured using URI syntax:

```
jms:destinationType:destinationName
```

with the following path and query parameters:

58.5.1. Path Parameters (2 parameters)

Name	Description	Default	Type
destinationType (common)	The kind of destination to use. Enum values: • queue • topic • temp-queue • temp-topic	queue	String
destinationName (common)	Required Name of the queue or topic to use as destination.		String

58.5.2. Query Parameters (95 parameters)

Name	Description	Default	Type
clientId (common)	Sets the JMS client ID to use. Note that this value, if specified, must be unique and can only be used by a single JMS connection instance. It is typically only required for durable topic subscriptions with JMS 1.1. If using Apache ActiveMQ you may prefer to use Virtual Topics instead.		String
connectionFactory (common)	The connection factory to be use. A connection factory must be configured either on the component or endpoint.		ConnectionFactory
disableReplyTo (common)	Specifies whether Camel ignores the JMSReplyTo header in messages. If true, Camel does not send a reply back to the destination specified in the JMSReplyTo header. You can use this option if you want Camel to consume from a route and you do not want Camel to automatically send back a reply message because another component in your code handles the reply message. You can also use this option if you want to use Camel as a proxy between different message brokers and you want to route message from one system to another.	false	boolean
durableSubscriptionName (common)	The durable subscriber name for specifying durable topic subscriptions. The clientId option must be configured as well.		String

Name	Description	Default	Type
jmsMessageType (common)	Allows you to force the use of a specific <code>javax.jms.Message</code> implementation for sending JMS messages. Possible values are: Bytes, Map, Object, Stream, Text. By default, Camel would determine which JMS message type to use from the In body type. This option allows you to specify it. Enum values: • Bytes • Map • Object • Stream • Text		JmsMessageType
replyTo (common)	Provides an explicit ReplyTo destination (overrides any incoming value of <code>Message.getJMSReplyTo()</code> in consumer).		String
testConnectionOnStartup (common)	Specifies whether to test the connection on startup. This ensures that when Camel starts that all the JMS consumers have a valid connection to the JMS broker. If a connection cannot be granted then Camel throws an exception on startup. This ensures that Camel is not started with failed connections. The JMS producers is tested as well.	false	boolean
acknowledgmentModeName (consumer)	The JMS acknowledgement name, which is one of: <code>SESSION_TRANSACTED</code>, <code>CLIENT_ACKNOWLEDGE</code>, <code>AUTO_ACKNOWLEDGE</code>, <code>DUPS_OK_ACKNOWLEDGE</code>. Enum values: • <code>SESSION_TRANSACTED</code> • <code>CLIENT_ACKNOWLEDGE</code> • <code>AUTO_ACKNOWLEDGE</code> • <code>DUPS_OK_ACKNOWLEDGE</code>	AUTO_ACKNOWLEDGE	String

Name	Description	Default	Type
artemisConsumerPriority (consumer)	Consumer priorities allow you to ensure that high priority consumers receive messages while they are active. Normally, active consumers connected to a queue receive messages from it in a round-robin fashion. When consumer priorities are in use, messages are delivered round-robin if multiple active consumers exist with the same high priority. Messages will only go to lower priority consumers when the high priority consumers do not have credit available to consume the message, or those high priority consumers have declined to accept the message (for instance because it does not meet the criteria of any selectors associated with the consumer).		int
asyncConsumer (consumer)	Whether the JmsConsumer processes the Exchange asynchronously. If enabled then the JmsConsumer may pickup the next message from the JMS queue, while the previous message is being processed asynchronously (by the Asynchronous Routing Engine). This means that messages may be processed not 100% strictly in order. If disabled (as default) then the Exchange is fully processed before the JmsConsumer picks up the next message from the JMS queue. Note if transacted has been enabled, then asyncConsumer=true does not run asynchronously, as transaction must be executed synchronously (Camel 3.0 may support async transactions).	false	boolean
autoStartup (consumer)	Specifies whether the consumer container should auto-startup.	true	boolean
cacheLevel (consumer)	Sets the cache level by ID for the underlying JMS resources. See cacheLevelName option for more details.		int

Name	Description	Default	Type
cacheLevelName (consumer)	Sets the cache level by name for the underlying JMS resources. Possible values are: <code>CACHE_AUTO</code>, <code>CACHE_CONNECTION</code>, <code>CACHE_CONSUMER</code>, <code>CACHE_NONE</code>, and <code>CACHE_SESSION</code>. The default setting is <code>CACHE_AUTO</code>. See the Spring documentation and Transactions Cache Levels for more information. Enum values: • <code>CACHE_AUTO</code> • <code>CACHE_CONNECTION</code> • <code>CACHE_CONSUMER</code> • <code>CACHE_NONE</code> • <code>CACHE_SESSION</code>	<code>CACHE_AUTO</code>	String
concurrentConsumers (consumer)	Specifies the default number of concurrent consumers when consuming from JMS (not for request/reply over JMS). See also the <code>maxMessagesPerTask</code> option to control dynamic scaling up/down of threads. When doing request/reply over JMS then the option <code>replyToConcurrentConsumers</code> is used to control number of concurrent consumers on the reply message listener.	1	int
maxConcurrentConsumers (consumer)	Specifies the maximum number of concurrent consumers when consuming from JMS (not for request/reply over JMS). See also the <code>maxMessagesPerTask</code> option to control dynamic scaling up/down of threads. When doing request/reply over JMS then the option <code>replyToMaxConcurrentConsumers</code> is used to control number of concurrent consumers on the reply message listener.		int
replyToDeliveryPersistent (consumer)	Specifies whether to use persistent delivery by default for replies.	true	boolean
selector (consumer)	Sets the JMS selector to use.		String

Name	Description	Default	Type
subscriptionDurable (consumer)	Set whether to make the subscription durable. The durable subscription name to be used can be specified through the <code>subscriptionName</code> property. Default is false. Set this to true to register a durable subscription, typically in combination with a <code>subscriptionName</code> value (unless your message listener class name is good enough as subscription name). Only makes sense when listening to a topic (pub-sub domain), therefore this method switches the <code>pubSubDomain</code> flag as well.	false	boolean
subscriptionName (consumer)	Set the name of a subscription to create. To be applied in case of a topic (pub-sub domain) with a shared or durable subscription. The subscription name needs to be unique within this client's JMS client id. Default is the class name of the specified message listener. Note: Only 1 concurrent consumer (which is the default of this message listener container) is allowed for each subscription, except for a shared subscription (which requires JMS 2.0).		String
subscriptionShared (consumer)	Set whether to make the subscription shared. The shared subscription name to be used can be specified through the <code>subscriptionName</code> property. Default is false. Set this to true to register a shared subscription, typically in combination with a <code>subscriptionName</code> value (unless your message listener class name is good enough as subscription name). Note that shared subscriptions may also be durable, so this flag can (and often will) be combined with <code>subscriptionDurable</code> as well. Only makes sense when listening to a topic (pub-sub domain), therefore this method switches the <code>pubSubDomain</code> flag as well. Requires a JMS 2.0 compatible message broker.	false	boolean
acceptMessagesWhileStopping (consumer (advanced))	Specifies whether the consumer accept messages while it is stopping. You may consider enabling this option, if you start and stop JMS routes at runtime, while there are still messages enqueued on the queue. If this option is false, and you stop the JMS route, then messages may be rejected, and the JMS broker would have to attempt redeliveries, which yet again may be rejected, and eventually the message may be moved at a dead letter queue on the JMS broker. To avoid this its recommended to enable this option.	false	boolean

Name	Description	Default	Type
allowReplyManagerQuickStop (consumer (advanced))	Whether the DefaultMessageListenerContainer used in the reply managers for request/reply messaging allow the DefaultMessageListenerContainer.runningAllowed flag to quick stop in case JmsConfiguration#isAcceptMessagesWhileStopping is enabled, and org.apache.camel.CamelContext is currently being stopped. This quick stop ability is enabled by default in the regular JMS consumers but to enable for reply managers you must enable this flag.	false	boolean
consumerType (consumer (advanced))	The consumer type to use, which can be one of: Simple, Default, or Custom. The consumer type determines which Spring JMS listener to use. Default will use org.springframework.jms.listener.DefaultMessageListenerContainer, Simple will use org.springframework.jms.listener.SimpleMessageListenerContainer. When Custom is specified, the MessageListenerContainerFactory defined by the messageListenerContainerFactory option will determine what org.springframework.jms.listener.AbstractMessageListenerContainer to use. Enum values: • Simple • Default • Custom	Default	ConsumerType

Name	Description	Default	Type
defaultTaskExecutorType (consumer (advanced))	Specifies what default TaskExecutor type to use in the DefaultMessageListenerContainer, for both consumer endpoints and the ReplyTo consumer of producer endpoints. Possible values: SimpleAsync (uses Spring's SimpleAsyncTaskExecutor) or ThreadPool (uses Spring's ThreadPoolTaskExecutor with optimal values - cached threadpool-like). If not set, it defaults to the previous behaviour, which uses a cached thread pool for consumer endpoints and SimpleAsync for reply consumers. The use of ThreadPool is recommended to reduce thread trash in elastic configurations with dynamically increasing and decreasing concurrent consumers. Enum values: • ThreadPool • SimpleAsync		DefaultTaskExecutorType
eagerLoadingOfProperties (consumer (advanced))	Enables eager loading of JMS properties and payload as soon as a message is loaded which generally is inefficient as the JMS properties may not be required but sometimes can catch early any issues with the underlying JMS provider and the use of JMS properties. See also the option eagerPoisonBody.	false	boolean
eagerPoisonBody (consumer (advanced))	If eagerLoadingOfProperties is enabled and the JMS message payload (JMS body or JMS properties) is poison (cannot be read/mapped), then set this text as the message body instead so the message can be processed (the cause of the poison are already stored as exception on the Exchange). This can be turned off by setting eagerPoisonBody=false. See also the option eagerLoadingOfProperties.	Poison JMS message due to \${exception.message}	String
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler

Name	Description	Default	Type
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • InOnly • InOut • InOptionalOut		ExchangePattern
exposeListenerSession (consumer (advanced))	Specifies whether the listener session should be exposed when consuming messages.	false	boolean
replyToSameDestinationAllowed (consumer (advanced))	Whether a JMS consumer is allowed to send a reply message to the same destination that the consumer is using to consume from. This prevents an endless loop by consuming and sending back the same message to itself.	false	boolean
taskExecutor (consumer (advanced))	Allows you to specify a custom task executor for consuming messages.		TaskExecutor
deliveryDelay (producer)	Sets delivery delay to use for send calls for JMS. This option requires JMS 2.0 compliant broker.	-1	long
deliveryMode (producer)	Specifies the delivery mode to be used. Possible values are those defined by <code>javax.jms.DeliveryMode</code>. <code>NON_PERSISTENT</code> = 1 and <code>PERSISTENT</code> = 2. Enum values: • 1 • 2		Integer
deliveryPersistent (producer)	Specifies whether persistent delivery is used by default.	true	boolean

Name	Description	Default	Type
explicitQosEnabled (producer)	Set if the deliveryMode, priority or timeToLive qualities of service should be used when sending messages. This option is based on Spring's JmsTemplate. The deliveryMode, priority and timeToLive options are applied to the current endpoint. This contrasts with the preserveMessageQos option, which operates at message granularity, reading QoS properties exclusively from the Camel In message headers.	false	Boolean
formatDateHeadersToIso8601 (producer)	Sets whether JMS date properties should be formatted according to the ISO 8601 standard.	false	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
preserveMessageQos (producer)	Set to true, if you want to send message using the QoS settings specified on the message, instead of the QoS settings on the JMS endpoint. The following three headers are considered JMSPriority, JMSDeliveryMode, and JMSExpiration. You can provide all or only some of them. If not provided, Camel will fall back to use the values from the endpoint instead. So, when using this option, the headers override the values from the endpoint. The explicitQosEnabled option, by contrast, will only use options set on the endpoint, and not values from the message header.	false	boolean

Name	Description	Default	Type
priority (producer)	Values greater than 1 specify the message priority when sending (where 1 is the lowest priority and 9 is the highest). The <code>explicitQosEnabled</code> option must also be enabled in order for this option to have any effect. Enum values: • 1 • 2 • 3 • 4 • 5 • 6 • 7 • 8 • 9	4	int
replyToConcurrentConsumers (producer)	Specifies the default number of concurrent consumers when doing request/reply over JMS. See also the <code>maxMessagesPerTask</code> option to control dynamic scaling up/down of threads.	1	int
replyToMaxConcurrentConsumers (producer)	Specifies the maximum number of concurrent consumers when using request/reply over JMS. See also the <code>maxMessagesPerTask</code> option to control dynamic scaling up/down of threads.		int
replyToOnTimeoutMaxConcurrentConsumers (producer)	Specifies the maximum number of concurrent consumers for continue routing when timeout occurred when using request/reply over JMS.	1	int
replyToOverride (producer)	Provides an explicit <code>ReplyTo</code> destination in the JMS message, which overrides the setting of <code>replyTo</code> . It is useful if you want to forward the message to a remote Queue and receive the reply message from the <code>ReplyTo</code> destination.		String

Name	Description	Default	Type
replyToType (producer)	Allows for explicitly specifying which kind of strategy to use for replyTo queues when doing request/reply over JMS. Possible values are: Temporary, Shared, or Exclusive. By default Camel will use temporary queues. However if replyTo has been configured, then Shared is used by default. This option allows you to use exclusive queues instead of shared ones. See Camel JMS documentation for more details, and especially the notes about the implications if running in a clustered environment, and the fact that Shared reply queues has lower performance than its alternatives Temporary and Exclusive. Enum values: • Temporary • Shared • Exclusive		ReplyToType
requestTimeout (producer)	The timeout for waiting for a reply when using the InOut Exchange Pattern (in milliseconds). The default is 20 seconds. You can include the header CamelJmsRequestTimeout to override this endpoint configured timeout value, and thus have per message individual timeout values. See also the requestTimeoutCheckerInterval option.	20000	long
timeToLive (producer)	When sending messages, specifies the time-to-live of the message (in milliseconds).	-1	long
allowAdditionalHeaders (producer (advanced))	This option is used to allow additional headers which may have values that are invalid according to JMS specification. For example some message systems such as WMQ do this with header names using prefix JMS_IBM_MQMD_ containing values with byte array or other invalid types. You can specify multiple header names separated by comma, and use as suffix for wildcard matching.		String
allowNullBody (producer (advanced))	Whether to allow sending messages with no body. If this option is false and the message body is null, then an JMSEException is thrown.	true	boolean

Name	Description	Default	Type
alwaysCopyMessage (producer (advanced))	If true, Camel will always make a JMS message copy of the message when it is passed to the producer for sending. Copying the message is needed in some situations, such as when a <code>replyToDestinationSelectorName</code> is set (incidentally, Camel will set the <code>alwaysCopyMessage</code> option to true, if a <code>replyToDestinationSelectorName</code> is set).	false	boolean
correlationProperty (producer (advanced))	When using InOut exchange pattern use this JMS property instead of <code>JMSCorrelationID</code> JMS property to correlate messages. If set messages will be correlated solely on the value of this property <code>JMSCorrelationID</code> property will be ignored and not set by Camel.		String
disableTimeToLive (producer (advanced))	Use this option to force disabling time to live. For example when you do request/reply over JMS, then Camel will by default use the <code>requestTimeout</code> value as time to live on the message being sent. The problem is that the sender and receiver systems have to have their clocks synchronized, so they are in sync. This is not always so easy to archive. So you can use <code>disableTimeToLive=true</code> to not set a time to live value on the sent message. Then the message will not expire on the receiver system. See below in section About time to live for more details.	false	boolean
forceSendOriginalMessage (producer (advanced))	When using <code>mapJmsMessage=false</code> Camel will create a new JMS message to send to a new JMS destination if you touch the headers (get or set) during the route. Set this option to true to force Camel to send the original JMS message that was received.	false	boolean
includeSentJMSMessageID (producer (advanced))	Only applicable when sending to JMS destination using InOnly (eg fire and forget). Enabling this option will enrich the Camel Exchange with the actual <code>JMSMessageID</code> that was used by the JMS client when the message was sent to the JMS destination.	false	boolean

Name	Description	Default	Type
replyToCacheLevelName (producer (advanced))	Sets the cache level by name for the reply consumer when doing request/reply over JMS. This option only applies when using fixed reply queues (not temporary). Camel will by default use: <code>CACHE_CONSUMER</code> for exclusive or shared w/ <code>replyToSelectorName</code>. And <code>CACHE_SESSION</code> for shared without <code>replyToSelectorName</code>. Some JMS brokers such as IBM WebSphere may require to set the <code>replyToCacheLevelName=CACHE_NONE</code> to work. Note: If using temporary queues then <code>CACHE_NONE</code> is not allowed, and you must use a higher value such as <code>CACHE_CONSUMER</code> or <code>CACHE_SESSION</code>. Enum values: ● <code>CACHE_AUTO</code> ● <code>CACHE_CONNECTION</code> ● <code>CACHE_CONSUMER</code> ● <code>CACHE_NONE</code> ● <code>CACHE_SESSION</code>		String
replyToSelectorName (producer (advanced))	Sets the JMS Selector using the fixed name to be used so you can filter out your own replies from the others when using a shared queue (that is, if you are not using a temporary reply queue).		String
streamMessageTypeEnabled (producer (advanced))	Sets whether <code>StreamMessage</code> type is enabled or not. Message payloads of streaming kind such as files, <code>InputStream</code> , etc will either be sent as <code>BytesMessage</code> or <code>StreamMessage</code> . This option controls which kind will be used. By default <code>BytesMessage</code> is used which enforces the entire message payload to be read into memory. By enabling this option the message payload is read into memory in chunks and each chunk is then written to the <code>StreamMessage</code> until no more data.	false	boolean
allowSerializedHeaders (advanced)	Controls whether or not to include serialized headers. Applies only when <code>transferExchange</code> is true. This requires that the objects are serializable. Camel will exclude any non-serializable objects and log it at WARN level.	false	boolean
artemisStreamingEnabled (advanced)	Whether optimizing for Apache Artemis streaming mode. This can reduce memory overhead when using Artemis with JMS <code>StreamMessage</code> types. This option must only be enabled if Apache Artemis is being used.	false	boolean

Name	Description	Default	Type
asyncStartListener (advanced)	Whether to startup the JmsConsumer message listener asynchronously, when starting a route. For example if a JmsConsumer cannot get a connection to a remote JMS broker, then it may block while retrying and/or failover. This will cause Camel to block while starting routes. By setting this option to true, you will let routes startup, while the JmsConsumer connects to the JMS broker using a dedicated thread in asynchronous mode. If this option is used, then beware that if the connection could not be established, then an exception is logged at WARN level, and the consumer will not be able to receive messages; You can then restart the route to retry.	false	boolean
asyncStopListener (advanced)	Whether to stop the JmsConsumer message listener asynchronously, when stopping a route.	false	boolean
destinationResolver (advanced)	A pluggable org.springframework.jms.support.destination.DestinationResolver that allows you to use your own resolver (for example, to lookup the real destination in a JNDI registry).		DestinationResolver
errorHandler (advanced)	Specifies a org.springframework.util.ErrorHandler to be invoked in case of any uncaught exceptions thrown while processing a Message. By default these exceptions will be logged at the WARN level, if no errorHandler has been configured. You can configure logging level and whether stack traces should be logged using errorHandlerLoggingLevel and errorHandlerLogStackTrace options. This makes it much easier to configure, than having to code a custom errorHandler.		ErrorHandler
exceptionListener (advanced)	Specifies the JMS Exception Listener that is to be notified of any underlying JMS exceptions.		ExceptionListener
headerFilterStrategy (advanced)	To use a custom HeaderFilterStrategy to filter header to and from Camel message.		HeaderFilterStrategy
idleConsumerLimit (advanced)	Specify the limit for the number of consumers that are allowed to be idle at any given time.	1	int

Name	Description	Default	Type
idleTaskExecutionLimit (advanced)	Specifies the limit for idle executions of a receive task, not having received any message within its execution. If this limit is reached, the task will shut down and leave receiving to other executing tasks (in the case of dynamic scheduling; see the <code>maxConcurrentConsumers</code> setting). There is additional doc available from Spring.	1	int
includeAllJMSXProperties (advanced)	Whether to include all JMSXxxx properties when mapping from JMS to Camel Message. Setting this to true will include properties such as JMSXAppID, and JMSXUserID etc. Note: If you are using a custom <code>headerFilterStrategy</code> then this option does not apply.	false	boolean
jmsKeyFormatStrategy (advanced)	Pluggable strategy for encoding and decoding JMS keys so they can be compliant with the JMS specification. Camel provides two implementations out of the box: default and passthrough. The default strategy will safely marshal dots and hyphens (. and -). The passthrough strategy leaves the key as is. Can be used for JMS brokers which do not care whether JMS header keys contain illegal characters. You can provide your own implementation of the <code>org.apache.camel.component.jms.JmsKeyFormatStrategy</code> and refer to it using the # notation. Enum values: • default • passthrough		JmsKeyFormatStrategy
mapJmsMessage (advanced)	Specifies whether Camel should auto map the received JMS message to a suited payload type, such as <code>javax.jms.TextMessage</code> to a String etc.	true	boolean
maxMessagesPerTask (advanced)	The number of messages per task. -1 is unlimited. If you use a range for concurrent consumers (eg min max), then this option can be used to set a value to eg 100 to control how fast the consumers will shrink when less work is required.	-1	int
messageConverter (advanced)	To use a custom Spring <code>org.springframework.jms.support.converter.MessageConverter</code> so you can be in control how to map to/from a <code>javax.jms.Message</code> .		MessageConverter

Name	Description	Default	Type
messageCreatedStrategy (advanced)	To use the given MessageCreatedStrategy which are invoked when Camel creates new instances of javax.jms.Message objects when Camel is sending a JMS message.		MessageCreatedStrategy
messageIdEnabled (advanced)	When sending, specifies whether message IDs should be added. This is just an hint to the JMS broker. If the JMS provider accepts this hint, these messages must have the message ID set to null; if the provider ignores the hint, the message ID must be set to its normal unique value.	true	boolean
messageListenerContainerFactory (advanced)	Registry ID of the MessageListenerContainerFactory used to determine what org.springframework.jms.listener.AbstractMessageListenerContainer to use to consume messages. Setting this will automatically set consumerType to Custom.		MessageListenerContainerFactory
messageTimestampEnabled (advanced)	Specifies whether timestamps should be enabled by default on sending messages. This is just an hint to the JMS broker. If the JMS provider accepts this hint, these messages must have the timestamp set to zero; if the provider ignores the hint the timestamp must be set to its normal value.	true	boolean
pubSubNoLocal (advanced)	Specifies whether to inhibit the delivery of messages published by its own connection.	false	boolean
receiveTimeout (advanced)	The timeout for receiving messages (in milliseconds).	1000	long
recoveryInterval (advanced)	Specifies the interval between recovery attempts, i.e. when a connection is being refreshed, in milliseconds. The default is 5000 ms, that is, 5 seconds.	5000	long
requestTimeoutCheckerInterval (advanced)	Configures how often Camel should check for timed out Exchanges when doing request/reply over JMS. By default Camel checks once per second. But if you must react faster when a timeout occurs, then you can lower this interval, to check more frequently. The timeout is determined by the option requestTimeout.	1000	long
synchronous (advanced)	Sets whether synchronous processing should be strictly used.	false	boolean

Name	Description	Default	Type
transferException (advanced)	If enabled and you are using Request Reply messaging (InOut) and an Exchange failed on the consumer side, then the caused Exception will be send back in response as a <code>javax.jms.ObjectMessage</code> . If the client is Camel, the returned Exception is rethrown. This allows you to use Camel JMS as a bridge in your routing - for example, using persistent queues to enable robust routing. Notice that if you also have <code>transferExchange</code> enabled, this option takes precedence. The caught exception is required to be serializable. The original Exception on the consumer side can be wrapped in an outer exception such as <code>org.apache.camel.RuntimeCamelException</code> when returned to the producer. Use this with caution as the data is using Java Object serialization and requires the received to be able to deserialize the data at Class level, which forces a strong coupling between the producers and consumer!.	false	boolean
transferExchange (advanced)	You can transfer the exchange over the wire instead of just the body and headers. The following fields are transferred: In body, Out body, Fault body, In headers, Out headers, Fault headers, exchange properties, exchange exception. This requires that the objects are serializable. Camel will exclude any non-serializable objects and log it at WARN level. You must enable this option on both the producer and consumer side, so Camel knows the payloads is an Exchange and not a regular payload. Use this with caution as the data is using Java Object serialization and requires the receiver to be able to deserialize the data at Class level, which forces a strong coupling between the producers and consumers having to use compatible Camel versions!.	false	boolean
useMessageIDAsCorrelationID (advanced)	Specifies whether <code>JMSMessageID</code> should always be used as <code>JMSCorrelationID</code> for InOut messages.	false	boolean
waitForProvisionCorrelationToBeUpdatedCounter (advanced)	Number of times to wait for provisional correlation id to be updated to the actual correlation id when doing request/reply over JMS and when the option <code>useMessageIDAsCorrelationID</code> is enabled.	50	int
waitForProvisionCorrelationToBeUpdatedThreadSleepingTime (advanced)	Interval in millis to sleep each time while waiting for provisional correlation id to be updated.	100	long

Name	Description	Default	Type
errorHandlerLoggingLevel (logging)	Allows to configure the default errorHandler logging level for logging uncaught exceptions. Enum values: ● TRACE ● DEBUG ● INFO ● WARN ● ERROR ● OFF	WARN	LogLevel
errorHandlerLogStackTrace (logging)	Allows to control whether stacktraces should be logged or not, by the default errorHandler.	true	boolean
password (security)	Password to use with the ConnectionFactory. You can also configure username/password directly on the ConnectionFactory.		String
username (security)	Username to use with the ConnectionFactory. You can also configure username/password directly on the ConnectionFactory.		String
transacted (transaction)	Specifies whether to use transacted mode.	false	boolean

Name	Description	Default	Type
transactedInOut (transaction)	Specifies whether InOut operations (request reply) default to using transacted mode. If this flag is set to true, then Spring JmsTemplate will have sessionTransacted set to true, and the acknowledgeMode as transacted on the JmsTemplate used for InOut operations. Note from Spring JMS: that within a JTA transaction, the parameters passed to createQueue, createTopic methods are not taken into account. Depending on the Java EE transaction context, the container makes its own decisions on these values. Analogously, these parameters are not taken into account within a locally managed transaction either, since Spring JMS operates on an existing JMS Session in this case. Setting this flag to true will use a short local JMS transaction when running outside of a managed transaction, and a synchronized local JMS transaction in case of a managed transaction (other than an XA transaction) being present. This has the effect of a local JMS transaction being managed alongside the main transaction (which might be a native JDBC transaction), with the JMS transaction committing right after the main transaction.	false	boolean
lazyCreateTransactionManager (transaction advanced))	If true, Camel will create a JmsTransactionManager, if there is no transactionManager injected when option transacted=true.	true	boolean
transactionManager (transaction advanced))	The Spring transaction manager to use.		PlatformTransactionManager
transactionName (transaction advanced))	The name of the transaction to use.		String
transactionTimeout (transaction advanced))	The timeout value of the transaction (in seconds), if using transacted mode.	-1	int

58.6. SAMPLES

JMS is used in many examples for other components as well. But we provide a few samples below to get started.

58.6.1. Receiving from JMS

In the following sample we configure a route that receives JMS messages and routes the message to a POJO:

```
from("jms:queue:foo").
  to("bean:myBusinessLogic");
```

You can of course use any of the EIP patterns so the route can be context based. For example, here's how to filter an order topic for the big spenders:

```
from("jms:topic:OrdersTopic").
  filter().method("myBean", "isGoldCustomer").
  to("jms:queue:BigSpendersQueue");
```

58.6.2. Sending to JMS

In the sample below we poll a file folder and send the file content to a JMS topic. As we want the content of the file as a **TextMessage** instead of a **BytesMessage**, we need to convert the body to a **String**:

```
from("file://orders").
  convertBodyTo(String.class).
  to("jms:topic:OrdersTopic");
```

58.6.3. Using Annotations

Camel also has annotations so you can use [POJO Consuming](#) and POJO Producing.

58.6.4. Spring DSL sample

The preceding examples use the Java DSL. Camel also supports Spring XML DSL. Here is the big spender sample using Spring DSL:

```
<route>
  <from uri="jms:topic:OrdersTopic"/>
  <filter>
    <method ref="myBean" method="isGoldCustomer"/>
    <to uri="jms:queue:BigSpendersQueue"/>
  </filter>
</route>
```

58.6.5. Other samples

JMS appears in many of the examples for other components and EIP patterns, as well in this Camel documentation. So feel free to browse the documentation.

58.6.6. Using JMS as a Dead Letter Queue storing Exchange

Normally, when using [JMS](#) as the transport, it only transfers the body and headers as the payload. If you want to use [JMS](#) with a [Dead Letter Channel](#), using a JMS queue as the Dead Letter Queue, then normally the caused Exception is not stored in the JMS message. You can, however, use the **transferExchange** option on the JMS dead letter queue to instruct Camel to store the entire Exchange in the queue as a **javax.jms.ObjectMessage** that holds a

org.apache.camel.support.DefaultExchangeHolder. This allows you to consume from the Dead Letter Queue and retrieve the caused exception from the Exchange property with the key **Exchange.EXCEPTION_CAUGHT**. The demo below illustrates this:

```
// setup error handler to use JMS as queue and store the entire Exchange
errorHandler(deadLetterChannel("jms:queue:dead?transferExchange=true"));
```

Then you can consume from the JMS queue and analyze the problem:

```
from("jms:queue:dead").to("bean:myErrorAnalyzer");

// and in our bean
String body = exchange.getIn().getBody();
Exception cause = exchange.getProperty(Exchange.EXCEPTION_CAUGHT, Exception.class);
// the cause message is
String problem = cause.getMessage();
```

58.6.7. Using JMS as a Dead Letter Channel storing error only

You can use JMS to store the cause error message or to store a custom body, which you can initialize yourself. The following example uses the Message Translator EIP to do a transformation on the failed exchange before it is moved to the [JMS](#) dead letter queue:

```
// we sent it to a seda dead queue first
errorHandler(deadLetterChannel("seda:dead"));

// and on the seda dead queue we can do the custom transformation before its sent to the JMS queue
from("seda:dead").transform(exceptionMessage()).to("jms:queue:dead");
```

Here we only store the original cause error message in the transform. You can, however, use any Expression to send whatever you like. For example, you can invoke a method on a Bean or use a custom processor.

58.7. MESSAGE MAPPING BETWEEN JMS AND CAMEL

Camel automatically maps messages between **javax.jms.Message** and **org.apache.camel.Message**.

When sending a JMS message, Camel converts the message body to the following JMS message types:

Body Type	JMS Message	Comment
String	javax.jms.TextMessage	
org.w3c.dom.Node	javax.jms.TextMessage	The DOM will be converted to String .
Map	javax.jms.MapMessage	
java.io.Serializable	javax.jms.ObjectMessage	

Body Type	JMS Message	Comment
<code>byte[]</code>	<code>javax.jms.BytesMessage</code>	
<code>java.io.File</code>	<code>javax.jms.BytesMessage</code>	
<code>java.io.Reader</code>	<code>javax.jms.BytesMessage</code>	
<code>java.io.InputStream</code>	<code>javax.jms.BytesMessage</code>	
<code>java.nio.ByteBuffer</code>	<code>javax.jms.BytesMessage</code>	

When receiving a JMS message, Camel converts the JMS message to the following body type:

JMS Message	Body Type
<code>javax.jms.TextMessage</code>	<code>String</code>
<code>javax.jms.BytesMessage</code>	<code>byte[]</code>
<code>javax.jms.MapMessage</code>	<code>Map<String, Object></code>
<code>javax.jms.ObjectMessage</code>	<code>Object</code>

58.7.1. Disabling auto-mapping of JMS messages

You can use the `mapJmsMessage` option to disable the auto-mapping above. If disabled, Camel will not try to map the received JMS message, but instead uses it directly as the payload. This allows you to avoid the overhead of mapping and let Camel just pass through the JMS message. For instance, it even allows you to route `javax.jms.ObjectMessage` JMS messages with classes you do **not** have on the classpath.

58.7.2. Using a custom MessageConverter

You can use the `messageConverter` option to do the mapping yourself in a Spring `org.springframework.jms.support.converter.MessageConverter` class.

For example, in the route below we use a custom message converter when sending a message to the JMS order queue:

```
from("file://inbox/order").to("jms:queue:order?messageConverter=#myMessageConverter");
```

You can also use a custom message converter when consuming from a JMS destination.

58.7.3. Controlling the mapping strategy selected

You can use the `jmsMessageType` option on the endpoint URL to force a specific message type for all messages.

In the route below, we poll files from a folder and send them as **javax.jms.TextMessage** as we have forced the JMS producer endpoint to use text messages:

```
from("file://inbox/order").to("jms:queue:order?jmsMessageType=Text");
```

You can also specify the message type to use for each message by setting the header with the key **CamelJmsMessageType**. For example:

```
from("file://inbox/order").setHeader("CamelJmsMessageType",
    JmsMessageType.Text).to("jms:queue:order");
```

The possible values are defined in the **enum** class, **org.apache.camel.jms.JmsMessageType**.

58.8. MESSAGE FORMAT WHEN SENDING

The exchange that is sent over the JMS wire must conform to the [JMS Message spec](#).

For the **exchange.in.header** the following rules apply for the header **keys**:

- Keys starting with **JMS** or **JMSX** are reserved.
- **exchange.in.headers** keys must be literals and all be valid Java identifiers (do not use dots in the key name).
- Camel replaces dots & hyphens and the reverse when consuming JMS messages:
 - . is replaced by ``DOT`` and the reverse replacement when Camel consumes the message.
 - is replaced by ``HYPHEN`` and the reverse replacement when Camel consumes the message.
- See also the option **jmsKeyFormatStrategy**, which allows use of your own custom strategy for formatting keys.

For the **exchange.in.header**, the following rules apply for the header **values**:

- The values must be primitives or their counter objects (such as **Integer**, **Long**, **Character**). The types, **String**, **CharSequence**, **Date**, **BigDecimal** and **BigInteger** are all converted to their **toString()** representation. All other types are dropped.

Camel will log with category **org.apache.camel.component.jms.JmsBinding** at **DEBUG** level if it drops a given header value. For example:

```
2008-07-09 06:43:04,046 [main          ] DEBUG JmsBinding
- Ignoring non primitive header: order of class:
org.apache.camel.component.jms.issues.DummyOrder with value: DummyOrder{orderId=333,
itemId=4444, quantity=2}
```

58.9. MESSAGE FORMAT WHEN RECEIVING

Camel adds the following properties to the **Exchange** when it receives a message:

Property	Type	Description
org.apache.camel.jms.replyDestination	javax.jms.Destination	The reply destination.

Camel adds the following JMS properties to the In message headers when it receives a JMS message:

Header	Type	Description
JMSCorrelationID	String	The JMS correlation ID.
JMSDeliveryMode	int	The JMS delivery mode.
JMSDestination	javax.jms.Destination	The JMS destination.
JMSExpiration	long	The JMS expiration.
JMSMessageID	String	The JMS unique message ID.
JMSPriority	int	The JMS priority (with 0 as the lowest priority and 9 as the highest).
JMSRedelivered	boolean	Is the JMS message redelivered.
JMSReplyTo	javax.jms.Destination	The JMS reply-to destination.
JMSTimestamp	long	The JMS timestamp.
JMSType	String	The JMS type.
JMSXGroupID	String	The JMS group ID.

As all the above information is standard JMS you can check the [JMS documentation](#) for further details.

58.10. ABOUT USING CAMEL TO SEND AND RECEIVE MESSAGES AND JMSREPLYTO

The JMS component is complex and you have to pay close attention to how it works in some cases. So this is a short summary of some of the areas/pitfalls to look for.

When Camel sends a message using its **JMSProducer**, it checks the following conditions:

- The message exchange pattern,
- Whether a **JMSReplyTo** was set in the endpoint or in the message headers,

- Whether any of the following options have been set on the JMS endpoint: **disableReplyTo**, **preserveMessageQos**, **explicitQosEnabled**.

All this can be a tad complex to understand and configure to support your use case.

58.10.1. JmsProducer

The **JmsProducer** behaves as follows, depending on configuration:

Exchange Pattern	Other options	Description
<i>InOut</i>	-	Camel will expect a reply, set a temporary JMSReplyTo , and after sending the message, it will start to listen for the reply message on the temporary queue.
<i>InOut</i>	JMSReplyTo is set	Camel will expect a reply and, after sending the message, it will start to listen for the reply message on the specified JMSReplyTo queue.
<i>InOnly</i>	-	Camel will send the message and not expect a reply.
<i>InOnly</i>	JMSReplyTo is set	By default, Camel discards the JMSReplyTo destination and clears the JMSReplyTo header before sending the message. Camel then sends the message and does not expect a reply. Camel logs this in the log at WARN level (changed to DEBUG level from Camel 2.6 onwards. You can use preserveMessageQos=true to instruct Camel to keep the JMSReplyTo . In all situations the JmsProducer does not expect any reply and thus continue after sending the message.

58.10.2. JmsConsumer

The **JmsConsumer** behaves as follows, depending on configuration:

Exchange Pattern	Other options	Description
<i>InOut</i>	-	Camel will send the reply back to the JMSReplyTo queue.
<i>InOnly</i>	-	Camel will not send a reply back, as the pattern is <i>InOnly</i> .
-	disableReplyTo=true	This option suppresses replies.

So pay attention to the message exchange pattern set on your exchanges.

If you send a message to a JMS destination in the middle of your route you can specify the exchange pattern to use, see more at [Request Reply](#).

This is useful if you want to send an **InOnly** message to a JMS topic:

```
from("activemq:queue:in")
  .to("bean:validateOrder")
  .to(ExchangePattern.InOnly, "activemq:topic:order")
  .to("bean:handleOrder");
```

58.11. REUSE ENDPOINT AND SEND TO DIFFERENT DESTINATIONS COMPUTED AT RUNTIME

If you need to send messages to a lot of different JMS destinations, it makes sense to reuse a JMS endpoint and specify the real destination in a message header. This allows Camel to reuse the same endpoint, but send to different destinations. This greatly reduces the number of endpoints created and economizes on memory and thread resources.

You can specify the destination in the following headers:

Header	Type	Description
CamelJmsDestination	javax.jms.Destination	A destination object.
CamelJmsDestinationName	String	The destination name.

For example, the following route shows how you can compute a destination at run time and use it to override the destination appearing in the JMS URL:

```
from("file://inbox")
  .to("bean:computeDestination")
  .to("activemq:queue:dummy");
```

The queue name, **dummy**, is just a placeholder. It must be provided as part of the JMS endpoint URL, but it will be ignored in this example.

In the **computeDestination** bean, specify the real destination by setting the **CamelJmsDestinationName** header as follows:

```
public void setJmsHeader(Exchange exchange) {
    String id = ....
    exchange.getIn().setHeader("CamelJmsDestinationName", "order:" + id);
}
```

Then Camel will read this header and use it as the destination instead of the one configured on the endpoint. So, in this example Camel sends the message to **activemq:queue:order:2**, assuming the **id** value was 2.

If both the **CamelJmsDestination** and the **CamelJmsDestinationName** headers are set, **CamelJmsDestination** takes priority. Keep in mind that the JMS producer removes both

CamelJmsDestination and **CamelJmsDestinationName** headers from the exchange and do not propagate them to the created JMS message in order to avoid the accidental loops in the routes (in scenarios when the message will be forwarded to the another JMS endpoint).

58.12. CONFIGURING DIFFERENT JMS PROVIDERS

You can configure your JMS provider in Spring XML as follows:

Basically, you can configure as many JMS component instances as you wish and give them a **unique name using the id attribute**. The preceding example configures an **activemq** component. You could do the same to configure MQSeries, TibCo, BEA, Sonic and so on.

Once you have a named JMS component, you can then refer to endpoints within that component using URIs. For example for the component name, **activemq**, you can then refer to destinations using the URI format, **activemq:[queue:]topic:]destinationName**. You can use the same approach for all other JMS providers.

This works by the SpringCamelContext lazily fetching components from the spring context for the scheme name you use for Endpoint URIs and having the Component resolve the endpoint URIs.

58.12.1. Using JNDI to find the ConnectionFactory

If you are using a J2EE container, you might need to look up JNDI to find the JMS **ConnectionFactory** rather than use the usual **<bean>** mechanism in Spring. You can do this using Spring's factory bean or the new Spring XML namespace. For example:

```
<bean id="weblogic" class="org.apache.camel.component.jms.JmsComponent">
  <property name="connectionFactory" ref="myConnectionFactory"/>
</bean>

<jee:jndi-lookup id="myConnectionFactory" jndi-name="jms/connectionFactory"/>
```

See [The jee schema](#) in the Spring reference documentation for more details about JNDI lookup.

58.13. CONCURRENT CONSUMING

A common requirement with JMS is to consume messages concurrently in multiple threads in order to make an application more responsive. You can set the **concurrentConsumers** option to specify the number of threads servicing the JMS endpoint, as follows:

```
from("jms:SomeQueue?concurrentConsumers=20").
  bean(MyClass.class);
```

You can configure this option in one of the following ways:

- On the **JmsComponent**,
- On the endpoint URI or,
- By invoking **setConcurrentConsumers()** directly on the **JmsEndpoint**.

58.13.1. Concurrent Consuming with async consumer

Notice that each concurrent consumer will only pickup the next available message from the JMS broker, when the current message has been fully processed. You can set the option **asyncConsumer=true** to let the consumer pickup the next message from the JMS queue, while the previous message is being processed asynchronously (by the Asynchronous Routing Engine). See more details in the table on top of the page about the **asyncConsumer** option.

```
from("jms:SomeQueue?concurrentConsumers=20&asyncConsumer=true").
    bean(MyClass.class);
```

58.14. REQUEST/REPLY OVER JMS

Camel supports request/reply over JMS. In essence the MEP of the Exchange should be **InOut** when you send a message to a JMS queue.

Camel offers a number of options to configure request/reply over JMS that influence performance and clustered environments. The table below summaries the options.

Option	Performance	Cluster	Description
Temporary	Fast	Yes	A temporary queue is used as reply queue, and automatic created by Camel. To use this do not specify a replyTo queue name. And you can optionally configure replyToType=Temporary to make it stand out that temporary queues are in use.
Shared	Slow	Yes	A shared persistent queue is used as reply queue. The queue must be created beforehand, although some brokers can create them on the fly such as Apache ActiveMQ. To use this you must specify the replyTo queue name. And you can optionally configure replyToType=Shared to make it stand out that shared queues are in use. A shared queue can be used in a clustered environment with multiple nodes running this Camel application at the same time. All using the same shared reply queue. This is possible because JMS Message selectors are used to correlate expected reply messages; this impacts performance though. JMS Message selectors is slower, and therefore not as fast as Temporary or Exclusive queues. See further below how to tweak this for better performance.

Option	Performance	Cluster	Description
Exclusive	Fast	No (*Yes)	An exclusive persistent queue is used as reply queue. The queue must be created beforehand, although some brokers can create them on the fly such as Apache ActiveMQ. To use this you must specify the <code>replyTo</code> queue name. And you must configure <code>replyToType=Exclusive</code> to instruct Camel to use exclusive queues, as Shared is used by default, if a <code>replyTo</code> queue name was configured. When using exclusive reply queues, then JMS Message selectors are not in use, and therefore other applications must not use this queue as well. An exclusive queue cannot be used in a clustered environment with multiple nodes running this Camel application at the same time; as we do not have control if the reply queue comes back to the same node that sent the request message; that is why shared queues use JMS Message selectors to make sure of this. Though if you configure each Exclusive reply queue with an unique name per node, then you can run this in a clustered environment. As then the reply message will be sent back to that queue for the given node, that awaits the reply message.
<code>replyToConcurrentConsumers</code>	Fast	Yes	Allows to process reply messages concurrently using concurrent message listeners in use. You can specify a range using the <code>replyToConcurrentConsumers</code> and <code>replyToMaxConcurrentConsumers</code> options. Notice: That using Shared reply queues may not work as well with concurrent listeners, so use this option with care.
<code>replyToMaxConcurrentConsumers</code>	Fast	Yes	Allows to process reply messages concurrently using concurrent message listeners in use. You can specify a range using the <code>replyToConcurrentConsumers</code> and <code>replyToMaxConcurrentConsumers</code> options. Notice: That using Shared reply queues may not work as well with concurrent listeners, so use this option with care.

The **JmsProducer** detects the **InOut** and provides a **JMSReplyTo** header with the reply destination to be used. By default Camel uses a temporary queue, but you can use the **`replyTo`** option on the endpoint to specify a fixed reply queue (see more below about fixed reply queue).

Camel will automatically setup a consumer which listen on the reply queue, so you should **not** do anything. This consumer is a Spring **DefaultMessageListenerContainer** which listen for replies. However it's fixed to 1 concurrent consumer. That means replies will be processed in sequence as there are only 1 thread to process the replies. You can configure the listener to use concurrent threads using the **`replyToConcurrentConsumers`** and **`replyToMaxConcurrentConsumers`** options. This allows you to easier configure this in Camel as shown below:

```
from(xxx)
.inOut().to("activemq:queue:foo?replyToConcurrentConsumers=5")
.to(yyy)
.to(zzz);
```

In this route we instruct Camel to route replies asynchronously using a thread pool with 5 threads.

58.14.1. Request/reply over JMS and using a shared fixed reply queue

You can use a fixed reply queue when doing request/reply over JMS as shown in the example below.

```
from(xxx)
.inOut().to("activemq:queue:foo?replyTo=bar")
.to(yyy)
```

In this example the fixed reply queue named "bar" is used. By default Camel assumes the queue is shared when using fixed reply queues, and therefore it uses a **JMSSelector** to only pickup the expected reply messages (eg based on the **JMSCorrelationID**). See next section for exclusive fixed reply queues. That means its not as fast as temporary queues. You can speedup how often Camel will pull for reply messages using the **receiveTimeout** option. By default its 1000 millis. So to make it faster you can set it to 250 millis to pull 4 times per second as shown:

```
from(xxx)
.inOut().to("activemq:queue:foo?replyTo=bar&receiveTimeout=250")
.to(yyy)
```

Notice this will cause the Camel to send pull requests to the message broker more frequent, and thus require more network traffic.

It is generally recommended to use temporary queues if possible.

58.14.2. Request/reply over JMS and using an exclusive fixed reply queue

In the previous example, Camel would anticipate the fixed reply queue named "bar" was shared, and thus it uses a **JMSSelector** to only consume reply messages which it expects. However there is a drawback doing this as the JMS selector is slower. Also the consumer on the reply queue is slower to update with new JMS selector ids. In fact it only updates when the **receiveTimeout** option times out, which by default is 1 second. So in theory the reply messages could take up till about 1 sec to be detected. On the other hand if the fixed reply queue is exclusive to the Camel reply consumer, then we can avoid using the JMS selectors, and thus be more performant. In fact as fast as using temporary queues. There is the **ReplyToType** option which you can configure to **Exclusive** to tell Camel that the reply queue is exclusive as shown in the example below:

```
from(xxx)
.inOut().to("activemq:queue:foo?replyTo=bar&replyToType=Exclusive")
.to(yyy)
```

Mind that the queue must be exclusive to each and every endpoint. So if you have two routes, then they each need an unique reply queue as shown in the next example:

```
from(xxx)
.inOut().to("activemq:queue:foo?replyTo=bar&replyToType=Exclusive")
.to(yyy)
```

```
from(aaa)
  .inOut().to("activemq:queue:order?replyTo=order.reply&replyToType=Exclusive")
  .to(bbb)
```

The same applies if you run in a clustered environment. Then each node in the cluster must use an unique reply queue name. As otherwise each node in the cluster may pickup messages which was intended as a reply on another node. For clustered environments its recommended to use shared reply queues instead.

58.15. SYNCHRONIZING CLOCKS BETWEEN SENDERS AND RECEIVERS

When doing messaging between systems, its desirable that the systems have synchronized clocks. For example when sending a [JMS](#) message, then you can set a time to live value on the message. Then the receiver can inspect this value, and determine if the message is already expired, and thus drop the message instead of consume and process it. However this requires that both sender and receiver have synchronized clocks. If you are using [ActiveMQ](#) then you can use the [timestamp plugin](#) to synchronize clocks.

58.16. ABOUT TIME TO LIVE

Read first above about synchronized clocks.

When you do request/reply (InOut) over [JMS](#) with Camel then Camel uses a timeout on the sender side, which is default 20 seconds from the **requestTimeout** option. You can control this by setting a higher/lower value. However the time to live value is still set on the message being send. So that requires the clocks to be synchronized between the systems. If they are not, then you may want to disable the time to live value being set. This is now possible using the **disableTimeToLive** option from **Camel 2.8** onwards. So if you set this option to **disableTimeToLive=true**, then Camel does **not** set any time to live value when sending [JMS](#) messages. **But** the request timeout is still active. So for example if you do request/reply over [JMS](#) and have disabled time to live, then Camel will still use a timeout by 20 seconds (the **requestTimeout** option). That option can of course also be configured. So the two options **requestTimeout** and **disableTimeToLive** gives you fine grained control when doing request/reply.

You can provide a header in the message to override and use as the request timeout value instead of the endpoint configured value. For example:

```
from("direct:someWhere")
  .to("jms:queue:foo?replyTo=bar&requestTimeout=30s")
  .to("bean:processReply");
```

In the route above we have a endpoint configured **requestTimeout** of 30 seconds. So Camel will wait up till 30 seconds for that reply message to come back on the bar queue. If no reply message is received then a **org.apache.camel.ExchangeTimedOutException** is set on the Exchange and Camel continues routing the message, which would then fail due the exception, and Camel's error handler reacts.

If you want to use a per message timeout value, you can set the header with key **org.apache.camel.component.jms.JmsConstants#JMS_REQUEST_TIMEOUT** which has constant value **"CamelJmsRequestTimeout"** with a timeout value as long type.

For example we can use a bean to compute the timeout value per individual message, such as calling the **"whatIsTheTimeout"** method on the service bean as shown below:

```
from("direct:someWhere")
```

```
.setHeader("CamelJmsRequestTimeout", method(ServiceBean.class, "whatIsTheTimeout"))
.to("jms:queue:foo?replyTo=bar&requestTimeout=30s")
.to("bean:processReply");
```

When you do fire and forget (InOut) over [JMS](#) with Camel then Camel by default does **not** set any time to live value on the message. You can configure a value by using the **timeToLive** option. For example to indicate a 5 sec., you set **timeToLive=5000**. The option **disableTimeToLive** can be used to force disabling the time to live, also for InOnly messaging. The **requestTimeout** option is not being used for InOnly messaging.

58.17. ENABLING TRANSACTED CONSUMPTION

A common requirement is to consume from a queue in a transaction and then process the message using the Camel route. To do this, just ensure that you set the following properties on the component/endpoint:

- **transacted** = true
- **transactionManager** = a *Transaction Manager* – typically the **JmsTransactionManager**

See the Transactional Client EIP pattern for further details.

Transactions and [Request Reply] over JMS

When using Request Reply over JMS you cannot use a single transaction; JMS will not send any messages until a commit is performed, so the server side won't receive anything at all until the transaction commits. Therefore to use [Request Reply](#) you must commit a transaction after sending the request and then use a separate transaction for receiving the response.

To address this issue the JMS component uses different properties to specify transaction use for oneway messaging and request reply messaging:

The **transacted** property applies **only** to the InOnly message Exchange Pattern (MEP).

You can leverage the [DMLC transacted session API](#) using the following properties on component/endpoint:

- **transacted** = true
- **lazyCreateTransactionManager** = false

The benefit of doing so is that the `cacheLevel` setting will be honored when using local transactions without a configured `TransactionManager`. When a `TransactionManager` is configured, no caching happens at DMLC level and it is necessary to rely on a pooled connection factory. For more details about this kind of setup, see [here](#) and [here](#).

58.18. USING JMSREPLYTO FOR LATE REPLIES

When using Camel as a JMS listener, it sets an Exchange property with the value of the `ReplyTo` **javax.jms.Destination** object, having the key **ReplyTo**. You can obtain this **Destination** as follows:

```
Destination replyDestination =
exchange.getIn().getHeader(JmsConstants.JMS_REPLY_DESTINATION, Destination.class);
```

And then later use it to send a reply using regular JMS or Camel.

```
// we need to pass in the JMS component, and in this sample we use ActiveMQ
JmsEndpoint endpoint = JmsEndpoint.newInstance(replyDestination, activeMQComponent);
// now we have the endpoint we can use regular Camel API to send a message to it
template.sendBody(endpoint, "Here is the late reply.");
```

A different solution to sending a reply is to provide the **replyDestination** object in the same Exchange property when sending. Camel will then pick up this property and use it for the real destination. The endpoint URI must include a dummy destination, however. For example:

```
// we pretend to send it to some non existing dummy queue
template.send("activemq:queue:dummy, new Processor() {
    public void process(Exchange exchange) throws Exception {
        // and here we override the destination with the ReplyTo destination object so the message is sent
        // to there instead of dummy
        exchange.getIn().setHeader(JmsConstants.JMS_DESTINATION, replyDestination);
        exchange.getIn().setBody("Here is the late reply.");
    }
}
```

58.19. USING A REQUEST TIMEOUT

In the sample below we send a Request Reply style message Exchange (we use the **requestBody** method = **InOut**) to the slow queue for further processing in Camel and we wait for a return reply:

58.20. SENDING AN INONLY MESSAGE AND KEEPING THE JMSREPLYTO HEADER

When sending to a [JMS](#) destination using **camel-jms** the producer will use the MEP to detect if its *InOnly* or *InOut* messaging. However there can be times where you want to send an *InOnly* message but keeping the **JMSReplyTo** header. To do so you have to instruct Camel to keep it, otherwise the **JMSReplyTo** header will be dropped.

For example to send an *InOnly* message to the foo queue, but with a **JMSReplyTo** with bar queue you can do as follows:

```
template.send("activemq:queue:foo?preserveMessageQos=true", new Processor() {
    public void process(Exchange exchange) throws Exception {
        exchange.getIn().setBody("World");
        exchange.getIn().setHeader("JMSReplyTo", "bar");
    }
});
```

Notice we use **preserveMessageQos=true** to instruct Camel to keep the **JMSReplyTo** header.

58.21. SETTING JMS PROVIDER OPTIONS ON THE DESTINATION

Some JMS providers, like IBM's WebSphere MQ need options to be set on the JMS destination. For example, you may need to specify the **targetClient** option. Since **targetClient** is a WebSphere MQ option and not a Camel URI option, you need to set that on the JMS destination name like so:

```
// ...
.setHeader("CamelJmsDestinationName", constant("queue:///MY_QUEUE?targetClient=1"))
.to("wmq:queue:MY_QUEUE?useMessageIDAsCorrelationID=true");
```

Some versions of WMQ won't accept this option on the destination name and you will get an exception like:

```
com.ibm.msg.client.jms.DetailedJMSEException: JMSCC0005: The specified
value 'MY_QUEUE?targetClient=1' is not allowed for
'XMSC_DESTINATION_NAME'
```

A workaround is to use a custom DestinationResolver:

```
JmsComponent wmq = new JmsComponent(connectionFactory);

wmq.setDestinationResolver(new DestinationResolver() {
    public Destination resolveDestinationName(Session session, String destinationName, boolean
    pubSubDomain) throws JMSEException {
        MQQueueSession wmqSession = (MQQueueSession) session;
        return wmqSession.createQueue("queue:/" + destinationName + "?targetClient=1");
    }
});
```

58.22. SPRING BOOT AUTO-CONFIGURATION

The component supports 99 options, which are listed below.

Name	Description	Default	Type
camel.component.jms.accept-messages-while-stopping	Specifies whether the consumer accept messages while it is stopping. You may consider enabling this option, if you start and stop JMS routes at runtime, while there are still messages enqueued on the queue. If this option is false, and you stop the JMS route, then messages may be rejected, and the JMS broker would have to attempt redeliveries, which yet again may be rejected, and eventually the message may be moved at a dead letter queue on the JMS broker. To avoid this its recommended to enable this option.	false	Boolean
camel.component.jms.acknowledgment-mode-name	The JMS acknowledgement name, which is one of: SESSION_TRANSACTED, CLIENT_ACKNOWLEDGE, AUTO_ACKNOWLEDGE, DUPS_OK_ACKNOWLEDGE.	AUTO_ACKNOWLEDGE	String

Name	Description	Default	Type
camel.component.jms.allow-additional-headers	This option is used to allow additional headers which may have values that are invalid according to JMS specification. For example some message systems such as WMQ do this with header names using prefix JMS_IBM_MQMD_ containing values with byte array or other invalid types. You can specify multiple header names separated by comma, and use as suffix for wildcard matching.		String
camel.component.jms.allow-auto-wired-connection-factory	Whether to auto-discover ConnectionFactory from the registry, if no connection factory has been configured. If only one instance of ConnectionFactory is found then it will be used. This is enabled by default.	true	Boolean
camel.component.jms.allow-auto-wired-destination-resolver	Whether to auto-discover DestinationResolver from the registry, if no destination resolver has been configured. If only one instance of DestinationResolver is found then it will be used. This is enabled by default.	true	Boolean
camel.component.jms.allow-null-body	Whether to allow sending messages with no body. If this option is false and the message body is null, then an JMSEException is thrown.	true	Boolean
camel.component.jms.allow-reply-manager-quick-stop	Whether the DefaultMessageListenerContainer used in the reply managers for request/reply messaging allow the DefaultMessageListenerContainer.runningAllowed flag to quick stop in case JmsConfiguration#isAcceptMessagesWhileStopping is enabled, and org.apache.camel.CamelContext is currently being stopped. This quick stop ability is enabled by default in the regular JMS consumers but to enable for reply managers you must enable this flag.	false	Boolean
camel.component.jms.allow-serialized-headers	Controls whether or not to include serialized headers. Applies only when transferExchange is true. This requires that the objects are serializable. Camel will exclude any non-serializable objects and log it at WARN level.	false	Boolean

Name	Description	Default	Type
camel.component.jms.always-copy-message	If true, Camel will always make a JMS message copy of the message when it is passed to the producer for sending. Copying the message is needed in some situations, such as when a <code>replyToDestinationSelectorName</code> is set (incidentally, Camel will set the <code>alwaysCopyMessage</code> option to true, if a <code>replyToDestinationSelectorName</code> is set).	false	Boolean
camel.component.jms.artemis-consumer-priority	Consumer priorities allow you to ensure that high priority consumers receive messages while they are active. Normally, active consumers connected to a queue receive messages from it in a round-robin fashion. When consumer priorities are in use, messages are delivered round-robin if multiple active consumers exist with the same high priority. Messages will only going to lower priority consumers when the high priority consumers do not have credit available to consume the message, or those high priority consumers have declined to accept the message (for instance because it does not meet the criteria of any selectors associated with the consumer).		Integer
camel.component.jms.artemis-streaming-enabled	Whether optimizing for Apache Artemis streaming mode. This can reduce memory overhead when using Artemis with JMS <code>StreamMessage</code> types. This option must only be enabled if Apache Artemis is being used.	false	Boolean
camel.component.jms.async-consumer	Whether the <code>JmsConsumer</code> processes the Exchange asynchronously. If enabled then the <code>JmsConsumer</code> may pickup the next message from the JMS queue, while the previous message is being processed asynchronously (by the Asynchronous Routing Engine). This means that messages may be processed not 100% strictly in order. If disabled (as default) then the Exchange is fully processed before the <code>JmsConsumer</code> picks up the next message from the JMS queue. Note if <code>transacted</code> has been enabled, then <code>asyncConsumer=true</code> does not run asynchronously, as transaction must be executed synchronously (Camel 3.0 may support async transactions).	false	Boolean

Name	Description	Default	Type
camel.component.jms.async-start-listener	Whether to startup the JmsConsumer message listener asynchronously, when starting a route. For example if a JmsConsumer cannot get a connection to a remote JMS broker, then it may block while retrying and/or failover. This will cause Camel to block while starting routes. By setting this option to true, you will let routes startup, while the JmsConsumer connects to the JMS broker using a dedicated thread in asynchronous mode. If this option is used, then beware that if the connection could not be established, then an exception is logged at WARN level, and the consumer will not be able to receive messages; You can then restart the route to retry.	false	Boolean
camel.component.jms.async-stop-listener	Whether to stop the JmsConsumer message listener asynchronously, when stopping a route.	false	Boolean
camel.component.jms.auto-startup	Specifies whether the consumer container should auto-startup.	true	Boolean
camel.component.jms.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.jms.cache-level	Sets the cache level by ID for the underlying JMS resources. See cacheLevelName option for more details.		Integer
camel.component.jms.cache-level-name	Sets the cache level by name for the underlying JMS resources. Possible values are: CACHE_AUTO, CACHE_CONNECTION, CACHE_CONSUMER, CACHE_NONE, and CACHE_SESSION. The default setting is CACHE_AUTO. See the Spring documentation and Transactions Cache Levels for more information.	CACHE_AUTO	String
camel.component.jms.client-id	Sets the JMS client ID to use. Note that this value, if specified, must be unique and can only be used by a single JMS connection instance. It is typically only required for durable topic subscriptions with JMS 1.1		String

Name	Description	Default	Type
camel.component.jms.concurrent-consumers	Specifies the default number of concurrent consumers when consuming from JMS (not for request/reply over JMS). See also the <code>maxMessagesPerTask</code> option to control dynamic scaling up/down of threads. When doing request/reply over JMS then the option <code>replyToConcurrentConsumers</code> is used to control number of concurrent consumers on the reply message listener.	1	Integer
camel.component.jms.configuration	To use a shared JMS configuration. The option is a <code>org.apache.camel.component.jms.JmsConfiguration</code> type.		JmsConfiguration
camel.component.jms.connection-factory	The connection factory to be use. A connection factory must be configured either on the component or endpoint. The option is a <code>javax.jms.ConnectionFactory</code> type.		ConnectionFactory
camel.component.jms.consumer-type	The consumer type to use, which can be one of: Simple, Default, or Custom. The consumer type determines which Spring JMS listener to use. Default will use <code>org.springframework.jms.listener.DefaultMessageListenerContainer</code> , Simple will use <code>org.springframework.jms.listener.SimpleMessageListenerContainer</code> . When Custom is specified, the <code>MessageListenerContainerFactory</code> defined by the <code>messageListenerContainerFactory</code> option will determine what <code>org.springframework.jms.listener.AbstractMessageListenerContainer</code> to use.		ConsumerType
camel.component.jms.correlation-property	When using InOut exchange pattern use this JMS property instead of <code>JMSCorrelationID</code> JMS property to correlate messages. If set messages will be correlated solely on the value of this property <code>JMSCorrelationID</code> property will be ignored and not set by Camel.		String

Name	Description	Default	Type
camel.component.jms.default-task-executor-type	Specifies what default TaskExecutor type to use in the DefaultMessageListenerContainer, for both consumer endpoints and the ReplyTo consumer of producer endpoints. Possible values: SimpleAsync (uses Spring's SimpleAsyncTaskExecutor) or ThreadPool (uses Spring's ThreadPoolTaskExecutor with optimal values - cached threadpool-like). If not set, it defaults to the previous behaviour, which uses a cached thread pool for consumer endpoints and SimpleAsync for reply consumers. The use of ThreadPool is recommended to reduce thread trash in elastic configurations with dynamically increasing and decreasing concurrent consumers.		DefaultTaskExecutorType
camel.component.jms.delivery-delay	Sets delivery delay to use for send calls for JMS. This option requires JMS 2.0 compliant broker.	-1	Long
camel.component.jms.delivery-mode	Specifies the delivery mode to be used. Possible values are those defined by javax.jms.DeliveryMode. NON_PERSISTENT = 1 and PERSISTENT = 2.		Integer
camel.component.jms.delivery-persistent	Specifies whether persistent delivery is used by default.	true	Boolean
camel.component.jms.destination-resolver	A pluggable org.springframework.jms.support.destination.DestinationResolver that allows you to use your own resolver (for example, to lookup the real destination in a JNDI registry). The option is a org.springframework.jms.support.destination.DestinationResolver type.		DestinationResolver
camel.component.jms.disable-reply-to	Specifies whether Camel ignores the JMSReplyTo header in messages. If true, Camel does not send a reply back to the destination specified in the JMSReplyTo header. You can use this option if you want Camel to consume from a route and you do not want Camel to automatically send back a reply message because another component in your code handles the reply message. You can also use this option if you want to use Camel as a proxy between different message brokers and you want to route message from one system to another.	false	Boolean

Name	Description	Default	Type
camel.component.jms.disable-time-to-live	Use this option to force disabling time to live. For example when you do request/reply over JMS, then Camel will by default use the requestTimeout value as time to live on the message being sent. The problem is that the sender and receiver systems have to have their clocks synchronized, so they are in sync. This is not always so easy to archive. So you can use disableTimeToLive=true to not set a time to live value on the sent message. Then the message will not expire on the receiver system. See below in section About time to live for more details.	false	Boolean
camel.component.jms.durable-subscription-name	The durable subscriber name for specifying durable topic subscriptions. The clientId option must be configured as well.		String
camel.component.jms.eager-loading-of-properties	Enables eager loading of JMS properties and payload as soon as a message is loaded which generally is inefficient as the JMS properties may not be required but sometimes can catch early any issues with the underlying JMS provider and the use of JMS properties. See also the option eagerPoisonBody.	false	Boolean
camel.component.jms.eager-poison-body	If eagerLoadingOfProperties is enabled and the JMS message payload (JMS body or JMS properties) is poison (cannot be read/mapped), then set this text as the message body instead so the message can be processed (the cause of the poison are already stored as exception on the Exchange). This can be turned off by setting eagerPoisonBody=false. See also the option eagerLoadingOfProperties.	Poison JMS message due to \${exception.message}	String
camel.component.jms.enabled	Whether to enable auto configuration of the jms component. This is enabled by default.		Boolean
camel.component.jms.error-handler	Specifies a org.springframework.util.ErrorHandler to be invoked in case of any uncaught exceptions thrown while processing a Message. By default these exceptions will be logged at the WARN level, if no errorHandler has been configured. You can configure logging level and whether stack traces should be logged using errorHandlerLogLevel and errorHandlerLogStackTrace options. This makes it much easier to configure, than having to code a custom errorHandler. The option is a org.springframework.util.ErrorHandler type.		ErrorHandler

Name	Description	Default	Type
<code>camel.component.jms.error-handler-log-stack-trace</code>	Allows to control whether stacktraces should be logged or not, by the default errorHandler.	true	Boolean
<code>camel.component.jms.error-handler-logging-level</code>	Allows to configure the default errorHandler logging level for logging uncaught exceptions.		LogLevel
<code>camel.component.jms.exception-listener</code>	Specifies the JMS Exception Listener that is to be notified of any underlying JMS exceptions. The option is a <code>javax.jms.ExceptionListener</code> type.		ExceptionListener
<code>camel.component.jms.explicit-qos-enabled</code>	Set if the deliveryMode, priority or timeToLive qualities of service should be used when sending messages. This option is based on Spring's <code>JmsTemplate</code> . The deliveryMode, priority and timeToLive options are applied to the current endpoint. This contrasts with the <code>preserveMessageQos</code> option, which operates at message granularity, reading QoS properties exclusively from the Camel In message headers.	false	Boolean
<code>camel.component.jms.expose-listener-session</code>	Specifies whether the listener session should be exposed when consuming messages.	false	Boolean
<code>camel.component.jms.force-send-original-message</code>	When using <code>mapJmsMessage=false</code> Camel will create a new JMS message to send to a new JMS destination if you touch the headers (get or set) during the route. Set this option to true to force Camel to send the original JMS message that was received.	false	Boolean
<code>camel.component.jms.format-date-headers-to-iso8601</code>	Sets whether JMS date properties should be formatted according to the ISO 8601 standard.	false	Boolean
<code>camel.component.jms.header-filter-strategy</code>	To use a custom <code>org.apache.camel.spi.HeaderFilterStrategy</code> to filter header to and from Camel message. The option is a <code>org.apache.camel.spi.HeaderFilterStrategy</code> type.		HeaderFilterStrategy
<code>camel.component.jms.idle-consumer-limit</code>	Specify the limit for the number of consumers that are allowed to be idle at any given time.	1	Integer

Name	Description	Default	Type
camel.component.jms.idle-task-execution-limit	Specifies the limit for idle executions of a receive task, not having received any message within its execution. If this limit is reached, the task will shut down and leave receiving to other executing tasks (in the case of dynamic scheduling; see the <code>maxConcurrentConsumers</code> setting). There is additional doc available from Spring.	1	Integer
camel.component.jms.include-all-jms-x-properties	Whether to include all JMSXxxx properties when mapping from JMS to Camel Message. Setting this to true will include properties such as JMSXAppID, and JMSXUserID etc. Note: If you are using a custom <code>headerFilterStrategy</code> then this option does not apply.	false	Boolean
camel.component.jms.include-sent-jms-message-id	Only applicable when sending to JMS destination using <code>InOnly</code> (eg fire and forget). Enabling this option will enrich the Camel Exchange with the actual <code>JMSMessageID</code> that was used by the JMS client when the message was sent to the JMS destination.	false	Boolean
camel.component.jms.jms-key-format-strategy	Pluggable strategy for encoding and decoding JMS keys so they can be compliant with the JMS specification. Camel provides two implementations out of the box: <code>default</code> and <code>passthrough</code> . The default strategy will safely marshal dots and hyphens (<code>.</code> and <code>-</code>). The <code>passthrough</code> strategy leaves the key as is. Can be used for JMS brokers which do not care whether JMS header keys contain illegal characters. You can provide your own implementation of the <code>org.apache.camel.component.jms.JmsKeyFormatStrategy</code> and refer to it using the <code>#</code> notation.		<code>JmsKeyFormatStrategy</code>
camel.component.jms.jms-message-type	Allows you to force the use of a specific <code>javax.jms.Message</code> implementation for sending JMS messages. Possible values are: <code>Bytes</code> , <code>Map</code> , <code>Object</code> , <code>Stream</code> , <code>Text</code> . By default, Camel would determine which JMS message type to use from the <code>In</code> body type. This option allows you to specify it.		<code>JmsMessageType</code>
camel.component.jms.lazy-create-transaction-manager	If true, Camel will create a <code>JmsTransactionManager</code> , if there is no <code>transactionManager</code> injected when option <code>transacted=true</code> .	true	Boolean

Name	Description	Default	Type
camel.component.jms.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.jms.map-jms-message	Specifies whether Camel should auto map the received JMS message to a suited payload type, such as javax.jms.TextMessage to a String etc.	true	Boolean
camel.component.jms.max-concurrent-consumers	Specifies the maximum number of concurrent consumers when consuming from JMS (not for request/reply over JMS). See also the maxMessagesPerTask option to control dynamic scaling up/down of threads. When doing request/reply over JMS then the option replyToMaxConcurrentConsumers is used to control number of concurrent consumers on the reply message listener.		Integer
camel.component.jms.max-messages-per-task	The number of messages per task. -1 is unlimited. If you use a range for concurrent consumers (eg min max), then this option can be used to set a value to eg 100 to control how fast the consumers will shrink when less work is required.	-1	Integer
camel.component.jms.message-converter	To use a custom Spring org.springframework.jms.support.converter.Message Converter so you can be in control how to map to/from a javax.jms.Message. The option is a org.springframework.jms.support.converter.Message Converter type.		MessageConverter
camel.component.jms.message-created-strategy	To use the given MessageCreatedStrategy which are invoked when Camel creates new instances of javax.jms.Message objects when Camel is sending a JMS message. The option is a org.apache.camel.component.jms.MessageCreatedStrategy type.		MessageCreatedStrategy

Name	Description	Default	Type
camel.component.jms.message-id-enabled	When sending, specifies whether message IDs should be added. This is just an hint to the JMS broker. If the JMS provider accepts this hint, these messages must have the message ID set to null; if the provider ignores the hint, the message ID must be set to its normal unique value.	true	Boolean
camel.component.jms.message-listener-container-factory	Registry ID of the MessageListenerContainerFactory used to determine what org.springframework.jms.listener.AbstractMessageListenerContainer to use to consume messages. Setting this will automatically set consumerType to Custom. The option is a org.apache.camel.component.jms.MessageListenerContainerFactory type.		MessageListenerContainerFactory
camel.component.jms.message-timestamp-enabled	Specifies whether timestamps should be enabled by default on sending messages. This is just an hint to the JMS broker. If the JMS provider accepts this hint, these messages must have the timestamp set to zero; if the provider ignores the hint the timestamp must be set to its normal value.	true	Boolean
camel.component.jms.password	Password to use with the ConnectionFactory. You can also configure username/password directly on the ConnectionFactory.		String
camel.component.jms.preserve-message-qos	Set to true, if you want to send message using the QoS settings specified on the message, instead of the QoS settings on the JMS endpoint. The following three headers are considered JMSPriority, JMSDeliveryMode, and JMSExpiration. You can provide all or only some of them. If not provided, Camel will fall back to use the values from the endpoint instead. So, when using this option, the headers override the values from the endpoint. The explicitQosEnabled option, by contrast, will only use options set on the endpoint, and not values from the message header.	false	Boolean
camel.component.jms.priority	Values greater than 1 specify the message priority when sending (where 1 is the lowest priority and 9 is the highest). The explicitQosEnabled option must also be enabled in order for this option to have any effect.	4	Integer
camel.component.jms.pub-sub-no-local	Specifies whether to inhibit the delivery of messages published by its own connection.	false	Boolean

Name	Description	Default	Type
camel.component.jms.queue-browse-strategy	To use a custom QueueBrowseStrategy when browsing queues. The option is a <code>org.apache.camel.component.jms.QueueBrowseStrategy</code> type.		QueueBrowseStrategy
camel.component.jms.receive-timeout	The timeout for receiving messages (in milliseconds). The option is a long type.	1000	Long
camel.component.jms.recovery-interval	Specifies the interval between recovery attempts, i.e. when a connection is being refreshed, in milliseconds. The default is 5000 ms, that is, 5 seconds. The option is a long type.	5000	Long
camel.component.jms.reply-to	Provides an explicit ReplyTo destination (overrides any incoming value of <code>Message.getJMSReplyTo()</code> in consumer).		String
camel.component.jms.reply-to-cache-level-name	Sets the cache level by name for the reply consumer when doing request/reply over JMS. This option only applies when using fixed reply queues (not temporary). Camel will by default use: <code>CACHE_CONSUMER</code> for exclusive or shared w/ <code>replyToSelectorName</code> . And <code>CACHE_SESSION</code> for shared without <code>replyToSelectorName</code> . Some JMS brokers such as IBM WebSphere may require to set the <code>replyToCacheLevelName=CACHE_NONE</code> to work. Note: If using temporary queues then <code>CACHE_NONE</code> is not allowed, and you must use a higher value such as <code>CACHE_CONSUMER</code> or <code>CACHE_SESSION</code> .		String
camel.component.jms.reply-to-concurrent-consumers	Specifies the default number of concurrent consumers when doing request/reply over JMS. See also the <code>maxMessagesPerTask</code> option to control dynamic scaling up/down of threads.	1	Integer
camel.component.jms.reply-to-delivery-persistent	Specifies whether to use persistent delivery by default for replies.	true	Boolean
camel.component.jms.reply-to-destination-selector-name	Sets the JMS Selector using the fixed name to be used so you can filter out your own replies from the others when using a shared queue (that is, if you are not using a temporary reply queue).		String

Name	Description	Default	Type
camel.component.jms.reply-to-max-concurrent-consumers	Specifies the maximum number of concurrent consumers when using request/reply over JMS. See also the <code>maxMessagesPerTask</code> option to control dynamic scaling up/down of threads.		Integer
camel.component.jms.reply-to-on-timeout-max-concurrent-consumers	Specifies the maximum number of concurrent consumers for continue routing when timeout occurred when using request/reply over JMS.	1	Integer
camel.component.jms.reply-to-override	Provides an explicit <code>ReplyTo</code> destination in the JMS message, which overrides the setting of <code>replyTo</code> . It is useful if you want to forward the message to a remote Queue and receive the reply message from the <code>ReplyTo</code> destination.		String
camel.component.jms.reply-to-same-destination-allowed	Whether a JMS consumer is allowed to send a reply message to the same destination that the consumer is using to consume from. This prevents an endless loop by consuming and sending back the same message to itself.	false	Boolean
camel.component.jms.reply-to-type	Allows for explicitly specifying which kind of strategy to use for <code>replyTo</code> queues when doing request/reply over JMS. Possible values are: <code>Temporary</code> , <code>Shared</code> , or <code>Exclusive</code> . By default Camel will use temporary queues. However if <code>replyTo</code> has been configured, then <code>Shared</code> is used by default. This option allows you to use exclusive queues instead of shared ones. See Camel JMS documentation for more details, and especially the notes about the implications if running in a clustered environment, and the fact that <code>Shared</code> reply queues has lower performance than its alternatives <code>Temporary</code> and <code>Exclusive</code> .		<code>ReplyToType</code>
camel.component.jms.request-timeout	The timeout for waiting for a reply when using the <code>InOut</code> Exchange Pattern (in milliseconds). The default is 20 seconds. You can include the header <code>CamelJmsRequestTimeout</code> to override this endpoint configured timeout value, and thus have per message individual timeout values. See also the <code>requestTimeoutCheckerInterval</code> option. The option is a long type.	20000	Long

Name	Description	Default	Type
camel.component.jms.request-timeout-checker-interval	Configures how often Camel should check for timed out Exchanges when doing request/reply over JMS. By default Camel checks once per second. But if you must react faster when a timeout occurs, then you can lower this interval, to check more frequently. The timeout is determined by the option requestTimeout. The option is a long type.	1000	Long
camel.component.jms.selector	Sets the JMS selector to use.		String
camel.component.jms.stream-message-type-enabled	Sets whether StreamMessage type is enabled or not. Message payloads of streaming kind such as files, InputStream, etc will either be sent as BytesMessage or StreamMessage. This option controls which kind will be used. By default BytesMessage is used which enforces the entire message payload to be read into memory. By enabling this option the message payload is read into memory in chunks and each chunk is then written to the StreamMessage until no more data.	false	Boolean
camel.component.jms.subscription-durable	Set whether to make the subscription durable. The durable subscription name to be used can be specified through the subscriptionName property. Default is false. Set this to true to register a durable subscription, typically in combination with a subscriptionName value (unless your message listener class name is good enough as subscription name). Only makes sense when listening to a topic (pub-sub domain), therefore this method switches the pubSubDomain flag as well.	false	Boolean
camel.component.jms.subscription-name	Set the name of a subscription to create. To be applied in case of a topic (pub-sub domain) with a shared or durable subscription. The subscription name needs to be unique within this client's JMS client id. Default is the class name of the specified message listener. Note: Only 1 concurrent consumer (which is the default of this message listener container) is allowed for each subscription, except for a shared subscription (which requires JMS 2.0).		String

Name	Description	Default	Type
camel.component.jms.subscription-shared	Set whether to make the subscription shared. The shared subscription name to be used can be specified through the subscriptionName property. Default is false. Set this to true to register a shared subscription, typically in combination with a subscriptionName value (unless your message listener class name is good enough as subscription name). Note that shared subscriptions may also be durable, so this flag can (and often will) be combined with subscriptionDurable as well. Only makes sense when listening to a topic (pub-sub domain), therefore this method switches the pubSubDomain flag as well. Requires a JMS 2.0 compatible message broker.	false	Boolean
camel.component.jms.synchronous	Sets whether synchronous processing should be strictly used.	false	Boolean
camel.component.jms.task-executor	Allows you to specify a custom task executor for consuming messages. The option is a org.springframework.core.task.TaskExecutor type.		TaskExecutor
camel.component.jms.test-connection-on-startup	Specifies whether to test the connection on startup. This ensures that when Camel starts that all the JMS consumers have a valid connection to the JMS broker. If a connection cannot be granted then Camel throws an exception on startup. This ensures that Camel is not started with failed connections. The JMS producers is tested as well.	false	Boolean
camel.component.jms.time-to-live	When sending messages, specifies the time-to-live of the message (in milliseconds).	-1	Long
camel.component.jms.transacted	Specifies whether to use transacted mode.	false	Boolean

Name	Description	Default	Type
camel.component.jms.transacted-in-out	Specifies whether InOut operations (request reply) default to using transacted mode. If this flag is set to true, then Spring JmsTemplate will have sessionTransacted set to true, and the acknowledgeMode as transacted on the JmsTemplate used for InOut operations. Note from Spring JMS: that within a JTA transaction, the parameters passed to createQueue, createTopic methods are not taken into account. Depending on the Java EE transaction context, the container makes its own decisions on these values. Analogously, these parameters are not taken into account within a locally managed transaction either, since Spring JMS operates on an existing JMS Session in this case. Setting this flag to true will use a short local JMS transaction when running outside of a managed transaction, and a synchronized local JMS transaction in case of a managed transaction (other than an XA transaction) being present. This has the effect of a local JMS transaction being managed alongside the main transaction (which might be a native JDBC transaction), with the JMS transaction committing right after the main transaction.	false	Boolean
camel.component.jms.transaction-manager	The Spring transaction manager to use. The option is a org.springframework.transaction.PlatformTransactionManager type.		PlatformTransactionManager
camel.component.jms.transaction-name	The name of the transaction to use.		String
camel.component.jms.transaction-timeout	The timeout value of the transaction (in seconds), if using transacted mode.	-1	Integer

Name	Description	Default	Type
camel.component.jms.transfer-exception	If enabled and you are using Request Reply messaging (InOut) and an Exchange failed on the consumer side, then the caused Exception will be send back in response as a javax.jms.ObjectMessage. If the client is Camel, the returned Exception is rethrown. This allows you to use Camel JMS as a bridge in your routing - for example, using persistent queues to enable robust routing. Notice that if you also have transferExchange enabled, this option takes precedence. The caught exception is required to be serializable. The original Exception on the consumer side can be wrapped in an outer exception such as org.apache.camel.RuntimeCamelException when returned to the producer. Use this with caution as the data is using Java Object serialization and requires the received to be able to deserialize the data at Class level, which forces a strong coupling between the producers and consumer!.	false	Boolean
camel.component.jms.transfer-exchange	You can transfer the exchange over the wire instead of just the body and headers. The following fields are transferred: In body, Out body, Fault body, In headers, Out headers, Fault headers, exchange properties, exchange exception. This requires that the objects are serializable. Camel will exclude any non-serializable objects and log it at WARN level. You must enable this option on both the producer and consumer side, so Camel knows the payloads is an Exchange and not a regular payload. Use this with caution as the data is using Java Object serialization and requires the receiver to be able to deserialize the data at Class level, which forces a strong coupling between the producers and consumers having to use compatible Camel versions!.	false	Boolean
camel.component.jms.use-message-i-d-as-correlation-i-d	Specifies whether JMSMessageID should always be used as JMSCorrelationID for InOut messages.	false	Boolean
camel.component.jms.username	Username to use with the ConnectionFactory. You can also configure username/password directly on the ConnectionFactory.		String

Name	Description	Default	Type
camel.component.jms.wait-for-provision-correlation-to-be-updated-counter	Number of times to wait for provisional correlation id to be updated to the actual correlation id when doing request/reply over JMS and when the option <code>useMessageIDAsCorrelationID</code> is enabled.	50	Integer
camel.component.jms.wait-for-provision-correlation-to-be-updated-thread-sleeping-time	Interval in millis to sleep each time while waiting for provisional correlation id to be updated. The option is a long type.	100	Long

CHAPTER 59. JOLOKIA

Jolokia starter integrates the Jolokia agent configuration in Spring Boot. It wraps the [Spring Support](#) by adding the default configurations to let the application work out-of-the-box without manually declaring Jolokia servers. This starter can be considered as an alternative to the [Jolokia JVM agent](#).

59.1. DEPENDENCIES

When using **camel-jolokia** with Red Hat build of Camel Spring Boot, add the following Maven dependency to your **pom.xml** to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-jolokia-starter</artifactId>
</dependency>
```

This exposes the Jolokia endpoint at <http://0.0.0.0:8778/jolokia/>. The agent can be configured according to the [Jolokia Spring support](#) page using the property prefix **camel.component.jolokia**. It is possible to configure **camel.component.jolokia.lookup-config=true**.

59.2. USING JOLOKIA AGENT

It is possible to configure the Jolokia server accessing the configuration map via properties according to the [Jolokia agent configuration](#) using **camel.component.jolokia.server-config** map configuration, that is, **camel.component.jolokia.server-config.port=8779** or **camel.component.jolokia.server-config.authMode=jaas**. The value of the **discoveryEnabled** configuration key is set to **true** on JVM local environment (not on Kubernetes), to allow the Hawtio process to discover the Jolokia agent. It is possible to disable the default configuration by setting the **camel.component.jolokia.server-config.discoveryEnabled=false**.

59.3. USING JOLOKIA RESTRICTOR

To avoid exposing all the JMX MBeans (see [Security](#) considerations), it provides a default Jolokia Restrictor that allows only Camel related data and some basic information from java. It is possible to avoid using the restrictor with the property **camel.component.jolokia.use-camel-restrictor=false** or to use your own custom one with the property **camel.component.jolokia.server-config.restrictorClass=org.example.MyRestrictor**.

An example to extend the provided restrictor is shown below.

Example

```
public class MyRestrictor extends CamelRestrictor {

  //getDefaultDomains() contains default domains, if you want to add some domain to the existing list
  @Override
  protected List<String> getAllowedDomains() {
    final List<String> newDomains = new ArrayList<>(getDefaultDomains());
    newDomains.add("my.domain");
    return newDomains;
  }
}
```

59.4. IMPLEMENTING SPRING JOLOKIA CONFIGURATION

The starter creates a default configuration according to the provided properties, that covers all the configuration for the Jolokia agent/server but if you want to use your custom **SpringJolokiaConfigHolder** implementation, it is possible to declare in the Spring context a Bean named **camelConfigHolder**.

Example of camelConfigHolder

```
@Bean("camelConfigHolder")
public SpringJolokiaConfigHolder myConfigHolder() {
    final SpringJolokiaConfigHolder myConfig = new SpringJolokiaConfigHolder();
    myConfig.setConfig(Map.of("threadNr", "5", "executor", "fixed"));
    return myConfig;
}
```

In this case, the executor configuration will be taken from the custom Bean if the same properties are not defined in the **application.properties**. This behaviour is also configurable with the property **camel.component.jolokia.config-from-properties-first=false**. It means that the configuration, in case the key is present in both **application.properties** and Bean implementation, uses the one from Bean. If the keys from properties and beans are not overridden each other, the simple merge will be applied. This way, the configuration properties allow to cover all the configurable aspect of the Jolokia server.

59.5. USING CAMEL LOG HANDLER HOLDER CONFIGURATION

There is a log configuration also provided in the starter that uses the slf4j implementation. You can change this configuration by providing a Bean named **camelLogHandlerHolder**.

Example of camelLogHandlerHolder

```
@Bean
@ConditionalOnMissingBean(name = "camelLogHandlerHolder")
public SpringJolokiaLogHandlerHolder myLogHandlerHolder() {
    final SpringJolokiaLogHandlerHolder stdoutHandlerHolder = new SpringJolokiaLogHandlerHolder();
    stdoutHandlerHolder.setType("stdout");
    return stdoutHandlerHolder;
}
```

The category for the Camel Spring Boot starter is **org.apache.camel.component.jolokia** while it is possible to configure level of the core Jolokia server with **org.jolokia**.

Example in application.properties

```
logging.level.org.apache.camel.component.jolokia = TRACE
logging.level.org.jolokia = TRACE
```

59.6. USING JOLOKIA CONFIGURATION IN KUBERNETES

The starter also provides some default configurations for a Kubernetes cluster environment. The starter checks the existence of a specific file to use as certification authority (**/var/run/secrets/kubernetes.io/serviceaccount/service-ca.crt**) and, if this file exists, it initializes the

server using TLS protocol and client authentication. So the endpoint become <https://0.0.0.0:8778/jolokia/>. It is possible to avoid this behaviour with the property **camel.component.jolokia.kubernetes-discover=false**.

The wrapped library Jolokia Spring Support provides the integration with the Spring Boot Actuator as per configuration where it is possible to retrieve information about Jolokia server. As any other actuator endpoint, it is possible to be excluded or disabled.

CHAPTER 60. JPA

Since Camel 1.0

Both producer and consumer are supported.

The JPA component enables you to store and retrieve Java objects from persistent storage using EJB 3's Java Persistence Architecture (JPA). Java Persistence Architecture (JPA) is a standard interface layer that wraps Object/Relational Mapping (ORM) products such as OpenJPA, Hibernate, TopLink.

60.1. DEPENDENCIES

When using **jpa** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-jpa-starter</artifactId>
</dependency>
```

60.2. SENDING TO THE ENDPOINT

You can store a Java entity bean in a database by sending it to a JPA producer endpoint. The body of the **In** message is assumed to be an entity bean (that is, a POJO with an `@Entity` annotation on it) or a collection or array of entity beans.

If the body is a List of entities, use **entityType=java.util.List** as a configuration passed to the producer endpoint.

If the body does not contain one of the previous listed types, put a Message Translator before the endpoint to perform the necessary conversion first.

You can use **query**, **namedQuery** or **nativeQuery** for the producer as well. For the value of the **parameters**, you can use the Simple expression which allows you to retrieve parameter values from Message body, header and etc. Those query can be used for retrieving a set of data with using **SELECT** JPQL/SQL statement as well as executing bulk update/delete with using **UPDATE/DELETE** JPQL/SQL statement. Please note that you need to specify **useExecuteUpdate** to **true** if you execute **UPDATE/DELETE** with **namedQuery** as camel doesn't look into the named query unlike **query** and **nativeQuery**.

60.3. CONSUMING FROM THE ENDPOINT

Consuming messages from a JPA consumer endpoint removes (or updates) entity beans in the database. This allows you to use a database table as a logical queue: consumers take messages from the queue and then delete/update them to logically remove them from the queue.

If you do not wish to delete the entity bean when it has been processed (and when routing is done), you can specify **consumeDelete=false** on the URI. This will result in the entity being processed each poll.

If you would rather perform some update on the entity to mark it as processed (such as to exclude it from a future query) then you can annotate a method with `@Consumed` which will be invoked on your entity bean when the entity bean when it has been processed (and when routing is done).

You can use [@PreConsumed](#) which will be invoked on your entity bean before it has been processed (before routing).

If you are consuming a lot (100K+) of rows and experience OutOfMemory problems you should set the `maximumResults` to sensible value.

60.4. URI FORMAT

```
jpa:entityClassName[?options]
```

For sending to the endpoint, the **entityClassName** is optional. If specified, it helps the [Type Converter](#) to ensure the body is of the correct type.

For consuming, the **entityClassName** is mandatory.

60.5. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

60.5.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).
- directly in the Java code.

60.5.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.

- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

60.6. COMPONENT OPTIONS

The JPA component supports 9 options, which are listed below.

Name	Description	Default	Type
aliases (common)	Maps an alias to a JPA entity class. The alias can then be used in the endpoint URI (instead of the fully qualified class name).		Map
entityManagerFactory (common)	To use the EntityManagerFactory. This is strongly recommended to configure.		EntityManagerFactory
joinTransaction (common)	The camel-jpa component will join transaction by default. You can use this option to turn this off, for example if you use LOCAL_RESOURCE and join transaction doesn't work with your JPA provider. This option can also be set globally on the JpaComponent, instead of having to set it on all endpoints.	true	boolean
sharedEntityManager (common)	Whether to use Spring's SharedEntityManager for the consumer/producer. Note in most cases joinTransaction should be set to false as this is not an EXTENDED EntityManager.	false	boolean
transactionManager (common)	To use the PlatformTransactionManager for managing transactions.		PlatformTransactionManager
transactionStrategy (common)	To use the TransactionStrategy for running the operations in a transaction.		TransactionStrategy
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

60.6.1. Endpoint Options

The JPA endpoint is configured using URI syntax:

```
jpa:entityType
```

with the following path and query parameters:

60.6.1.1. Path Parameters (1 parameters)

Name	Description	Default	Type
entityType (common)	Required Entity class name.		Class

60.6.1.2. Query Parameters (44 parameters)

Name	Description	Default	Type
------	-------------	---------	------

Name	Description	Default	Type
joinTransaction (common)	The camel-jpa component will join transaction by default. You can use this option to turn this off, for example if you use LOCAL_RESOURCE and join transaction doesn't work with your JPA provider. This option can also be set globally on the JpaComponent, instead of having to set it on all endpoints.	true	boolean
maximumResults (common)	Set the maximum number of results to retrieve on the Query.	-1	int
namedQuery (common)	To use a named query.		String
nativeQuery (common)	To use a custom native query. You may want to use the option resultClass also when using native queries.		String
persistenceUnit (common)	Required The JPA persistence unit used by default.	camel	String
query (common)	To use a custom query.		String
resultClass (common)	Defines the type of the returned payload (we will call entityManager.createNativeQuery(nativeQuery, resultClass) instead of entityManager.createNativeQuery(nativeQuery)). Without this option, we will return an object array. Only has an affect when using in conjunction with native query when consuming data.		Class
consumeDelete (consumer)	If true, the entity is deleted after it is consumed; if false, the entity is not deleted.	true	boolean
consumeLockEntity (consumer)	Specifies whether or not to set an exclusive lock on each entity bean while processing the results from polling.	true	boolean
deleteHandler (consumer)	To use a custom DeleteHandler to delete the row after the consumer is done processing the exchange.		DeleteHandler

Name	Description	Default	Type
lockModeType (consumer)	To configure the lock mode on the consumer. Enum values: • READ • WRITE • OPTIMISTIC • OPTIMISTIC_FORCE_INCREMENT • PESSIMISTIC_READ • PESSIMISTIC_WRITE • PESSIMISTIC_FORCE_INCREMENT • NONE	PESSIMISTIC_WRITE	LockModeType
maxMessagesPerPoll (consumer)	An integer value to define the maximum number of messages to gather per poll. By default, no maximum is set. Can be used to avoid polling many thousands of messages when starting up the server. Set a value of 0 or negative to disable.		int
preDeleteHandler (consumer)	To use a custom Pre-DeleteHandler to delete the row after the consumer has read the entity.		DeleteHandler
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean
skipLockedEntity (consumer)	To configure whether to use NOWAIT on lock and silently skip the entity.	false	boolean
transacted (consumer)	Whether to run the consumer in transacted mode, by which all messages will either commit or rollback, when the entire batch has been processed. The default behavior (false) is to commit all the previously successfully processed messages, and only rollback the last failed message.	false	boolean

Name	Description	Default	Type
bridgeErrorHandler (consumer (advanced))	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer (advanced))	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		<code>ExceptionHandler</code>
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: • <code>InOnly</code> • <code>InOut</code> • <code>InOptionalOut</code>		<code>ExchangePattern</code>
parameters (consumer (advanced))	This key/value mapping is used for building the query parameters. It is expected to be of the generic type <code>java.util.Map</code> where the keys are the named parameters of a given JPA query and the values are their corresponding effective values you want to select for. When it's used for producer, Simple expression can be used as a parameter value. It allows you to retrieve parameter values from the message body, header and etc.		<code>Map</code>
pollStrategy (consumer (advanced))	A pluggable <code>org.apache.camel.PollingConsumerPollingStrategy</code> allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		<code>PollingConsumerPollStrategy</code>
findEntity (producer)	If enabled then the producer will find a single entity by using the message body as key and <code>entityType</code> as the class type. This can be used instead of a query to find a single entity.	false	boolean

Name	Description	Default	Type
flushOnSend (producer)	Flushes the EntityManager after the entity bean has been persisted.	true	boolean
remove (producer)	Indicates to use entityManager.remove(entity).	false	boolean
useExecuteUpdate (producer)	To configure whether to use executeUpdate() when producer executes a query. When you use INSERT, UPDATE or DELETE statement as a named query, you need to specify this option to 'true'.		Boolean
usePersist (producer)	Indicates to use entityManager.persist(entity) instead of entityManager.merge(entity). Note: entityManager.persist(entity) doesn't work for detached entities (where the EntityManager has to execute an UPDATE instead of an INSERT query)!.	false	boolean
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
usePassedInEntityManager (producer (advanced))	If set to true, then Camel will use the EntityManager from the header JpaConstants.ENTITY_MANAGER instead of the configured entity manager on the component/endpoint. This allows end users to control which entity manager will be in use.	false	boolean
entityManagerProperties (advanced)	Additional properties for the entity manager to use.		Map
sharedEntityManager (advanced)	Whether to use Spring's SharedEntityManager for the consumer/producer. Note in most cases joinTransaction should be set to false as this is not an EXTENDED EntityManager.	false	boolean
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.		int

Name	Description	Default	Type
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.		int
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.		int
delay (scheduler)	Milliseconds before the next poll.	500	long
greedy (scheduler)	If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts.	1000	long
repeatCount (scheduler)	Specifies a maximum limit of number of fires. So if you set it to 1, the scheduler will only fire once. If you set it to 5, it will only fire five times. A value of zero or negative means fire forever.	0	long
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that. Enum values: ● TRACE ● DEBUG ● INFO ● WARN ● ERROR ● OFF	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz component. Use value spring or quartz for built in scheduler.	none	Object

Name	Description	Default	Type
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for initialDelay and delay options. Enum values: • NANoseconds • MICROseconds • MILLIseconds • SECONDS • MINUTES • HOURS • DAYS	MILLIS ECON DS	TimeUnit
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.	true	boolean

60.7. MESSAGE HEADERS

The JPA component supports 2 message header(s), which are listed below:

Name	Description	Default	Type
CamelEntityManager (common) Constant: ENTITY_MANAGER	The JPA EntityManager object.		EntityManager
CamelJpaParameters (producer) Constant: link: JPA_PARAMETER_HEADERS_HEADER	Alternative way for passing query parameters as an Exchange header.		Map

60.8. CONFIGURING ENTITYMANAGERFACTORY

It is recommended to configure the JPA component to use a specific **EntityManagerFactory** instance. If failed to do so each **JpaEndpoint** will auto create their own instance of **EntityManagerFactory** which most often is not what you want.

For example, you can instantiate a JPA component that references the **myEMFactory** entity manager factory, as follows:

```
<bean id="jpa" class="org.apache.camel.component.jpa.JpaComponent">
  <property name="entityManagerFactory" ref="myEMFactory"/>
</bean>
```

The **JpaComponent** automatically looks up the **EntityManagerFactory** from the Registry which means you do not need to configure this on the **JpaComponent** as shown above. You only need to do so if there is ambiguity, in which case Camel will log a WARN.

60.9. CONFIGURING TRANSACTIONMANAGER

The **JpaComponent** automatically looks up the **TransactionManager** from the Registry. If Camel won't find any **TransactionManager** instance registered, it will also look up for the **TransactionTemplate** and try to extract **TransactionManager** from it.

If none **TransactionTemplate** is available in the registry, **JpaEndpoint** will auto create their own instance of **TransactionManager** which most often is not what you want.

If more than single instance of the **TransactionManager** is found, Camel will log a WARN. In such cases you might want to instantiate and explicitly configure a JPA component that references the **myTransactionManager** transaction manager, as follows:

```
<bean id="jpa" class="org.apache.camel.component.jpa.JpaComponent">
  <property name="entityManagerFactory" ref="myEMFactory"/>
  <property name="transactionManager" ref="myTransactionManager"/>
</bean>
```

60.10. USING A CONSUMER WITH A NAMED QUERY

For consuming only selected entities, you can use the **namedQuery** URI query option. First, you have to define the named query in the JPA Entity class:

```
@Entity
@NamedQuery(name = "step1", query = "select x from MultiSteps x where x.step = 1")
public class MultiSteps {
  ...
}
```

After that you can define a consumer uri as shown below:

```
from("jpa://org.apache.camel.examples.MultiSteps?namedQuery=step1")
.to("bean:myBusinessLogic");
```

60.11. USING A CONSUMER WITH A QUERY

For consuming only selected entities, you can use the **query** URI query option. You only have to define the query option:

```
from("jpa://org.apache.camel.examples.MultiSteps?query=select o from  
org.apache.camel.examples.MultiSteps o where o.step = 1")  
.to("bean:myBusinessLogic");
```

60.12. USING A CONSUMER WITH A NATIVE QUERY

For consuming only selected entities, you can use the **nativeQuery** URI query option. You only have to define the native query option:

```
from("jpa://org.apache.camel.examples.MultiSteps?nativeQuery=select * from MultiSteps where step  
= 1")  
.to("bean:myBusinessLogic");
```

If you use the native query option, you will receive an object array in the message body.

60.13. USING A PRODUCER WITH A NAMED QUERY

For retrieving selected entities or execute bulk update/delete, you can use the **namedQuery** URI query option. First, you have to define the named query in the JPA Entity class:

```
@Entity  
@NamedQuery(name = "step1", query = "select x from MultiSteps x where x.step = 1")  
public class MultiSteps {  
    ...  
}
```

After that you can define a producer uri as shown below:

```
from("direct:namedQuery")  
.to("jpa://org.apache.camel.examples.MultiSteps?namedQuery=step1");
```

Note that you need to specify **useExecuteUpdate** option to **true** to execute **UPDATE/DELETE** statement as a named query.

60.14. USING A PRODUCER WITH A QUERY

For retrieving selected entities or execute bulk update/delete, you can use the **query** URI query option. You only have to define the query option:

```
from("direct:query")  
.to("jpa://org.apache.camel.examples.MultiSteps?query=select o from  
org.apache.camel.examples.MultiSteps o where o.step = 1");
```

60.15. USING A PRODUCER WITH A NATIVE QUERY

For retrieving selected entities or execute bulk update/delete, you can use the **nativeQuery** URI query option. You only have to define the native query option:

```
from("direct:nativeQuery")
.to("jpa://org.apache.camel.examples.MultiSteps?
resultClass=org.apache.camel.examples.MultiSteps&nativeQuery=select * from MultiSteps where
step = 1");
```

If you use the native query option without specifying **resultClass**, you will receive an object array in the message body.

60.16. USING THE JPA-BASED IDEMPOTENT REPOSITORY

The Idempotent Consumer from the [EIP patterns](#) is used to filter out duplicate messages. A JPA-based idempotent repository is provided.

To use the JPA based idempotent repository.

Procedure

1. Set up a **persistence-unit** in the persistence.xml file.
2. Set up a **org.springframework.orm.jpa.JpaTemplate** which is used by the **org.apache.camel.processor.idempotent.jpa.JpaMessageIdRepository**.
3. Configure the error formatting macro: snippet: java.lang.IndexOutOfBoundsException: Index: 20, Size: 20
4. Configure the idempotent repository as **org.apache.camel.processor.idempotent.jpa.JpaMessageIdRepository**.
5. Create the JPA idempotent repository in the Spring XML file as shown below:

```
<camelContext xmlns="http://camel.apache.org/schema/spring">
  <route id="JpaMessageIdRepositoryTest">
    <from uri="direct:start" />
    <idempotentConsumer idempotentRepository="jpaStore">
      <header>messageId</header>
      <to uri="mock:result" />
    </idempotentConsumer>
  </route>
</camelContext>
```

When running this Camel component tests inside your IDE

If you run the [tests of this component](#) directly inside your IDE, and not through Maven, then you could see exceptions like these:

```
org.springframework.transaction.CannotCreateTransactionException: Could not open JPA
EntityManager for transaction; nested exception is
<openjpa-2.2.1-r422266:1396819 nonfatal user error>
org.apache.openjpa.persistence.ArgumentException: This configuration disallows runtime
optimization,
but the following listed types were not enhanced at build time or at class load time with a javaagent:
"org.apache.camel.examples.SendEmail".
```

```

    at
    org.springframework.orm.jpa.JpaTransactionManager.doBegin(JpaTransactionManager.java:427)
    at
    org.springframework.transaction.support.AbstractPlatformTransactionManager.getTransaction(Abstract
    PlatformTransactionManager.java:371)
    at
    org.springframework.transaction.support.TransactionTemplate.execute(TransactionTemplate.java:127)

    at org.apache.camel.processor.jpa.JpaRouteTest.cleanupRepository(JpaRouteTest.java:96)
    at org.apache.camel.processor.jpa.JpaRouteTest.createCamelContext(JpaRouteTest.java:67)
    at org.apache.camel.test.junit5.CamelTestSupport.doSetUp(CamelTestSupport.java:238)
    at org.apache.camel.test.junit5.CamelTestSupport.setUp(CamelTestSupport.java:208)

```

The problem here is that the source has been compiled or recompiled through your IDE and not through Maven, which would [enhance the byte-code at build time](#). To overcome this you need to enable [dynamic byte-code enhancement of OpenJPA](#). For example, assuming the current OpenJPA version being used in Camel is 2.2.1, to run the tests inside your IDE you would need to pass the following argument to the JVM:

```
-javaagent:<path_to_your_local_m2_cache>/org/apache/openjpa/openjpa/2.2.1/openjpa-2.2.1.jar
```

60.17. SPRING BOOT AUTO-CONFIGURATION

The component supports 10 options, which are listed below.

Name	Description	Default	Type
camel.component.jpa.aliaes	Maps an alias to a JPA entity class. The alias can then be used in the endpoint URI (instead of the fully qualified class name).		Map
camel.component.jpa.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.jpa.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.jpa.enabled	Whether to enable auto configuration of the jpa component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.jpa.entity-manager-factory	To use the EntityManagerFactory. This is strongly recommended to configure. The option is a <code>javax.persistence.EntityManagerFactory</code> type.		EntityManagerFactory
camel.component.jpa.join-transaction	The camel-jpa component will join transaction by default. You can use this option to turn this off, for example if you use <code>LOCAL_RESOURCE</code> and join transaction doesn't work with your JPA provider. This option can also be set globally on the <code>JpaComponent</code> , instead of having to set it on all endpoints.	true	Boolean
camel.component.jpa.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow <code>CamelContext</code> and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.jpa.shared-entity-manager	Whether to use Spring's <code>SharedEntityManager</code> for the consumer/producer. Note in most cases <code>joinTransaction</code> should be set to false as this is not an <code>EXTENDED EntityManager</code> .	false	Boolean
camel.component.jpa.transaction-manager	To use the <code>PlatformTransactionManager</code> for managing transactions. The option is a <code>org.springframework.transaction.PlatformTransactionManager</code> type.		PlatformTransactionManager
camel.component.jpa.transaction-strategy	To use the <code>TransactionStrategy</code> for running the operations in a transaction. The option is a <code>org.apache.camel.component.jpa.TransactionStrategy</code> type.		TransactionStrategy

CHAPTER 61. JQ

Since Camel 3.18

Camel supports [JQ](#) to allow using [Expression](#) or [Predicate](#) on JSON messages.

61.1. DEPENDENCIES

When using **jq with** Red Hat build of Camel Spring Boot, use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-jq-starter</artifactId>
</dependency>
```

61.2. JQ OPTIONS

The JQ language supports 4 options, which are listed below.

Name	Default	Java Type	Description
headerName		String	Name of header to use as input, instead of the message body It has as higher precedent than the propertyName if both are set.
propertyName		String	Name of property to use as input, instead of the message body. It has a lower precedent than the headerName if both are set.
resultType		String	Sets the class of the result type (type from output).
trim	true	Boolean	Whether to trim the value to remove leading and trailing whitespaces and line breaks.

61.3. EXAMPLES

For example, you can use JQ in a [Predicate](#) with the [Content Based Router EIP](#) .

```
from("queue:books.new")
  .choice()
    .when().jq(".store.book.price < 10")
      .to("jms:queue:book.cheap")
    .when().jq(".store.book.price < 30")
      .to("jms:queue:book.average")
    .otherwise()
      .to("jms:queue:book.expensive");
```

61.4. MESSAGE BODY TYPES

Camel JQ leverages **camel-jackson** for type conversion. To enable camel-jackson POJO type conversion, refer to the [Camel Jackson](#) documentation.

61.5. USING HEADER AS INPUT

By default, JQ uses the message body as the input source. However, you can also use a header as input by specifying the **headerName** option.

For example to count the number of books from a JSON document that was stored in a header named **books** you can do:

```
from("direct:start")
  .setHeader("numberOfBooks")
  .jq(".store.books | length", int.class, "books")
  .to("mock:result");
```

61.6. CAMEL SUPPLIED JQ FUNCTIONS

The camel-jq adds the following functions:

- **header** – Allow to access the Message header in a JQ expression.

For example, to set the property foo with the value from the Message header `MyHeader`:

```
from("direct:start")
  .transform()
  .jq(".foo = header(\"MyHeader\")")
  .to("mock:result");
```

61.7. SPRING BOOT AUTO-CONFIGURATION

The component supports 4 options, which are listed below.

Name	Description	Default	Type
camel.language.jq.enabled	Whether to enable auto configuration of the jq language. This is enabled by default.		Boolean
camel.language.jq.header-name	Name of header to use as input, instead of the message body It has as higher precedent than the propertyName if both are set.		String
camel.language.jq.property-name	Name of property to use as input, instead of the message body. It has a lower precedent than the headerName if both are set.		String
camel.language.jq.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean

CHAPTER 62. JSLT

Since Camel 3.1

Only producer is supported

The JSLT component allows you to process a JSON messages using an [JSLT](#) expression. This can be ideal when doing JSON to JSON transformation or querying data.

62.1. DEPENDENCIES

When using **jslt** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-jslt-starter</artifactId>
</dependency>
```

62.2. URI FORMAT

```
jslt:specName[?options]
```

Where **specName** is the classpath-local URI of the specification to invoke; or the complete URL of the remote specification (eg: [file://folder/myfile.vm](#)).

62.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

62.3.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).
- directly in the Java code.

62.3.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

62.4. COMPONENT OPTIONS

The JSLT component supports 5 options, which are listed below.

Name	Description	Default	Type
allowTemplateFromHeader (producer)	Whether to allow to use resource template from header or not (default false). Enabling this allows to specify dynamic templates via message header. However this can be seen as a potential security vulnerability if the header is coming from a malicious user, so use this with care.	false	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean

Name	Description	Default	Type
functions (advanced)	JSLT can be extended by plugging in functions written in Java.		Collection
objectFilter (advanced)	JSLT can be extended by plugging in a custom jslt object filter.		JsonFilter

62.4.1. Endpoint Options

The JSLT endpoint is configured using URI syntax:

```
jslt:resourceUri
```

with the following path and query parameters:

62.4.1.1. Path Parameters (1 parameters)

Name	Description	Default	Type
resourceUri (producer)	Required Path to the resource. You can prefix with: classpath, file, http, ref, or bean. classpath, file and http loads the resource using these protocols (classpath is default). ref will lookup the resource in the registry. bean will call a method on a bean to be used as the resource. For bean you can specify the method name after dot, eg bean:myBean.myMethod.		String

62.4.1.2. Query Parameters (7 parameters)

Name	Description	Default	Type
allowContextMap All (producer)	Sets whether the context map should allow access to all details. By default only the message body and headers can be accessed. This option can be enabled for full access to the current Exchange and CamelContext. Doing so impose a potential security risk as this opens access to the full power of CamelContext API.	false	boolean

Name	Description	Default	Type
allowTemplateFromHeader (producer)	Whether to allow to use resource template from header or not (default false). Enabling this allows to specify dynamic templates via message header. However this can be seen as a potential security vulnerability if the header is coming from a malicious user, so use this with care.	false	boolean
contentCache (producer)	Sets whether to use resource content cache or not.	false	boolean
mapBigDecimalAsFloats (producer)	If true, the mapper will use the USE_BIG_DECIMAL_FOR_FLOATS in serialization features.	false	boolean
objectMapper (producer)	Setting a custom JSON Object Mapper to be used.		ObjectMapper
prettyPrint (common)	If true, JSON in output message is pretty printed.	false	boolean
lazyStartProducer (producer (advanced))	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

62.5. MESSAGE HEADERS

The JSLT component supports 2 message header(s), which is/are listed below:

Name	Description	Default	Type
CamelJsItString (producer) Constant: <code>HEADER_JSLT_STRING</code>	The JSLT Template as String.		String

Name	Description	Default	Type
CamelJsltResourceUri (producer) Constant: HEADER_JSLT_RESOURCE_URI	The resource URI.		String

62.6. PASSING VALUES TO JSLT

Camel can supply exchange information as variables when applying a JSLT expression on the body. The available variables from the **Exchange** are:

name	value
headers	The headers of the In message as a json object
exchange.properties	The Exchange properties as a json object. exchange is the name of the variable and <i>properties</i> is the path to the exchange properties. Available if allowContextMapAll option is true.

All the values that cannot be converted to json with Jackson are denied and will not be available in the jslt expression.

For example, the header named "type" and the exchange property "instance" can be accessed like

```
{
  "type": $headers.type,
  "instance": $exchange.properties.instance
}
```

62.7. SAMPLES

The sample example is as given below.

```
from("activemq:My.Queue").
  to("jslt:com/acme/MyResponse.json");
```

And a file based resource:

```
from("activemq:My.Queue").
  to("jslt:file://myfolder/MyResponse.json?contentCache=true").
  to("activemq:Another.Queue");
```

You can also specify which JSLT expression the component should use dynamically via a header, so for example:

```
from("direct:in").
```

```
setHeader("CamelJsltResourceUri").constant("path/to/my/spec.json").
to("jslt:dummy?allowTemplateFromHeader=true");
```

Or send whole jslt expression via header: (suitable for querying)

```
from("direct:in").
setHeader("CamelJsltString").constant(".published").
to("jslt:dummy?allowTemplateFromHeader=true");
```

Passing exchange properties to the jslt expression can be done like this

```
from("direct:in").
to("jslt:com/acme/MyResponse.json?allowContextMapAll=true");
```

62.8. SPRING BOOT AUTO-CONFIGURATION

The component supports 6 options, which are listed below.

Name	Description	Default	Type
camel.component.jslt.allow-template-from-header	Whether to allow to use resource template from header or not (default false). Enabling this allows to specify dynamic templates via message header. However this can be seen as a potential security vulnerability if the header is coming from a malicious user, so use this with care.	false	Boolean
camel.component.jslt.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.jslt.enabled	Whether to enable auto configuration of the jslt component. This is enabled by default.		Boolean
camel.component.jslt.functions	JSLT can be extended by plugging in functions written in Java.		Collection

Name	Description	Default	Type
camel.component.jslt.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.jslt.object-filter	JSLT can be extended by plugging in a custom jslt object filter. The option is a <code>com.schibsted.spt.data.jslt.filters.JsonFilter</code> type.		JsonFilter

CHAPTER 63. JSON GSON

Gson is a Data Format which uses the [Gson Library](#).

```
from("activemq:My.Queue").
  marshal().json(JsonLibrary.Gson).
  to("mqseries:Another.Queue");
```

63.1. DEPENDENCIES

When using **json-gson** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-gson-starter</artifactId>
</dependency>
```

63.2. GSON OPTIONS

The JSON Gson dataformat supports 3 options, which are listed below.

Name	Default	Java Type	Description
prettyPrint		Boolean	To enable pretty printing output nicely formatted. Is by default false.
unmarshalType		String	Class name of the java type to use when unmarshalling.
contentTypeHeader		Boolean	Whether the data format should set the Content-Type header with the type from the data format. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON.

63.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 4 options, which are listed below.

Name	Description	Default	Type
camel.dataformat.json-gson.content-type-header	Whether the data format should set the Content-Type header with the type from the data format. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON.	true	Boolean

Name	Description	Default	Type
<code>camel.dataformat.json-gson.enabled</code>	Whether to enable auto configuration of the json-gson data format. This is enabled by default.		Boolean
<code>camel.dataformat.json-gson.pretty-print</code>	To enable pretty printing output nicely formatted. Is by default false.	false	Boolean
<code>camel.dataformat.json-gson.unmarshal-type</code>	Class name of the java type to use when unmarshalling.		String

CHAPTER 64. JSON JACKSON

Jackson is a Data Format which uses the [Jackson Library](#)

```
from("activemq:My.Queue").
  marshal().json(JsonLibrary.Jackson).
  to("mqseries:Another.Queue");
```

64.1. DEPENDENCIES

When using **json-jackson** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-jackson-starter</artifactId>
</dependency>
```

64.2. JACKSON OPTIONS

The JSON Jackson dataformat supports 20 options, which are listed below.

Name	Default	Java Type	Description
objectMapper		String	Lookup and use the existing ObjectMapper with the given id when using Jackson.
useDefaultObjectMapper		Boolean	Whether to lookup and use default Jackson ObjectMapper from the registry.
prettyPrint		Boolean	To enable pretty printing output nicely formatted. Is by default false.
unmarshalType		String	Class name of the java type to use when unmarshalling.

Name	Default	Java Type	Description
jsonView		String	When marshalling a POJO to JSON you might want to exclude certain fields from the JSON output. With Jackson you can use JSON views to accomplish this. This option is to refer to the class which has JsonView annotations.
include		String	If you want to marshal a pojo to JSON, and the pojo has some fields with null values. And you want to skip these null values, you can set this option to NON_NULL.
allowJmsType		Boolean	Used for JMS users to allow the JMSType header from the JMS spec to specify a FQN classname to use to unmarshal to.
collectionType		String	Refers to a custom collection type to lookup in the registry to use. This option should rarely be used, but allows to use different collection types than java.util.Collection based as default.

Name	Default	Java Type	Description
<code>useList</code>		Boolean	To unmarshal to a List of Map or a List of Pojo.
<code>moduleClassNames</code>		String	To use custom Jackson modules <code>com.fasterxml.jackson.databind.Module</code> specified as a String with FQN class names. Multiple classes can be separated by comma.
<code>moduleRefs</code>		String	To use custom Jackson modules referred from the Camel registry. Multiple modules can be separated by comma.
<code>enableFeatures</code>		String	Set of features to enable on the Jackson <code>com.fasterxml.jackson.databind.ObjectMapper</code> . The features should be a name that matches a enum from <code>com.fasterxml.jackson.databind.SerializationFeature</code> , <code>com.fasterxml.jackson.databind.DeserializationFeature</code> , or <code>com.fasterxml.jackson.databind.MapperFeature</code> . Multiple features can be separated by comma.

Name	Default	Java Type	Description
disableFeatures		String	Set of features to disable on the Jackson <code>com.fasterxml.jackson.databind.ObjectMapper</code> . The features should be a name that matches a enum from <code>com.fasterxml.jackson.databind.SerializationFeature</code> , <code>com.fasterxml.jackson.databind.DeserializationFeature</code> , or <code>com.fasterxml.jackson.databind.MapperFeature</code> . Multiple features can be separated by comma.
allowUnmarshalType		Boolean	If enabled then Jackson is allowed to attempt to use the <code>CamelJacksonUnmarshalType</code> header during the unmarshalling. This should only be enabled when desired to be used.
timezone		String	If set then Jackson will use the <code>Timezone</code> when marshalling/unmarshalling. This option will have no effect on the others <code>JsonDataFormat</code> , like <code>gson</code> , <code>fastjson</code> and <code>xstream</code> .

Name	Default	Java Type	Description
autoDiscoverObjectMapper		Boolean	If set to true then Jackson will lookup for an objectMapper into the registry.
contentTypeHeader		Boolean	Whether the data format should set the Content-Type header with the type from the data format. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON.
schemaResolver		String	Optional schema resolver used to lookup schemas for the data in transit.
autoDiscoverSchemaResolver		Boolean	When not disabled, the SchemaResolver will be looked up into the registry.
namingStrategy		String	If set then Jackson will use the the defined Property Naming Strategy. Possible values are: LOWER_CAMEL_CASE, LOWER_DOT_CASE, LOWER_CASE, KEBAB_CASE, SNAKE_CASE and UPPER_CAMEL_CASE.

64.3. USING CUSTOM OBJECTMAPPER

You can configure **JacksonDataFormat** to use a custom **ObjectMapper** in case you need more control of the mapping configuration.

If you setup a single **ObjectMapper** in the registry, then Camel will automatic lookup and use this **ObjectMapper**. For example if you use Spring Boot, then Spring Boot can provide a default **ObjectMapper** for you if you have Spring MVC enabled. And this would allow Camel to detect that there is one bean of **ObjectMapper** class type in the Spring Boot bean registry and then use it. When this happens you should set a **INFO** logging from Camel.

64.4. USING JACKSON FOR AUTOMATIC TYPE CONVERSION

The **camel-jackson** module allows integrating Jackson as a [Type Converter](#). This works in a similar way to [JAXB](#) that integrates with Camel's type converter.

To use this **camel-jackson** must be enabled, which is done by setting the following options on the **CamelContext** global options, as shown:

```
@Bean
CamelContextConfiguration contextConfiguration() {
    return new CamelContextConfiguration() {
        @Override
        public void beforeApplicationStart(CamelContext context) {
            // Enable Jackson JSON type converter.
            context.getGlobalOptions().put(JacksonConstants.ENABLE_TYPE_CONVERTER, "true");
            // Allow Jackson JSON to convert to pojo types also
            // (by default Jackson only converts to String and other simple types)
            getContext().getGlobalOptions().put(JacksonConstants.TYPE_CONVERTER_TO_POJO,
"true");
        }

        @Override
        public void afterApplicationStart(CamelContext camelContext) {

        }
    };
}
```

The **camel-jackson** type converter integrates with [JAXB](#) which means you can annotate POJO class with **JAXB** annotations that Jackson can use. You can also use Jackson's own annotations on your POJO classes.

64.5. SPRING BOOT AUTO-CONFIGURATION

The component supports 21 options, which are listed below.

Name	Description	Default	Type
<code>camel.dataformat.json-jackson.allow-jms-type</code>	Used for JMS users to allow the JMSType header from the JMS spec to specify a FQN classname to use to unmarshal to.	false	Boolean
<code>camel.dataformat.json-jackson.allow-unmarshall-type</code>	If enabled then Jackson is allowed to attempt to use the CamelJacksonUnmarshalType header during the unmarshalling. This should only be enabled when desired to be used.	false	Boolean
<code>camel.dataformat.json-jackson.auto-discover-object-mapper</code>	If set to true then Jackson will lookup for an objectMapper into the registry.	false	Boolean
<code>camel.dataformat.json-jackson.auto-discover-schema-resolver</code>	When not disabled, the SchemaResolver will be looked up into the registry.	true	Boolean
<code>camel.dataformat.json-jackson.collection-type</code>	Refers to a custom collection type to lookup in the registry to use. This option should rarely be used, but allows to use different collection types than java.util.Collection based as default.		String
<code>camel.dataformat.json-jackson.content-type-header</code>	Whether the data format should set the Content-Type header with the type from the data format. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON.	true	Boolean
<code>camel.dataformat.json-jackson.disable-features</code>	Set of features to disable on the Jackson com.fasterxml.jackson.databind.ObjectMapper. The features should be a name that matches a enum from com.fasterxml.jackson.databind.SerializationFeature, com.fasterxml.jackson.databind.DeserializationFeature, or com.fasterxml.jackson.databind.MapperFeature. Multiple features can be separated by comma.		String
<code>camel.dataformat.json-jackson.enable-features</code>	Set of features to enable on the Jackson com.fasterxml.jackson.databind.ObjectMapper. The features should be a name that matches a enum from com.fasterxml.jackson.databind.SerializationFeature, com.fasterxml.jackson.databind.DeserializationFeature, or com.fasterxml.jackson.databind.MapperFeature. Multiple features can be separated by comma.		String

Name	Description	Default	Type
<code>camel.dataformat.json-jackson.enabled</code>	Whether to enable auto configuration of the json-jackson data format. This is enabled by default.		Boolean
<code>camel.dataformat.json-jackson.include</code>	If you want to marshal a pojo to JSON, and the pojo has some fields with null values. And you want to skip these null values, you can set this option to <code>NON_NULL</code> .		String
<code>camel.dataformat.json-jackson.json-view</code>	When marshalling a POJO to JSON you might want to exclude certain fields from the JSON output. With Jackson you can use JSON views to accomplish this. This option is to refer to the class which has <code>JsonView</code> annotations.		String
<code>camel.dataformat.json-jackson.module-class-names</code>	To use custom Jackson modules <code>com.fasterxml.jackson.databind.Module</code> specified as a String with FQN class names. Multiple classes can be separated by comma.		String
<code>camel.dataformat.json-jackson.module-refs</code>	To use custom Jackson modules referred from the Camel registry. Multiple modules can be separated by comma.		String
<code>camel.dataformat.json-jackson.naming-strategy</code>	If set then Jackson will use the the defined Property Naming Strategy. Possible values are: <code>LOWER_CAMEL_CASE</code> , <code>LOWER_DOT_CASE</code> , <code>LOWER_CASE</code> , <code>KEBAB_CASE</code> , <code>SNAKE_CASE</code> and <code>UPPER_CAMEL_CASE</code> .		String
<code>camel.dataformat.json-jackson.object-mapper</code>	Lookup and use the existing ObjectMapper with the given id when using Jackson.		String
<code>camel.dataformat.json-jackson.pretty-print</code>	To enable pretty printing output nicely formatted. Is by default false.	false	Boolean
<code>camel.dataformat.json-jackson.schema-resolver</code>	Optional schema resolver used to lookup schemas for the data in transit.		String

Name	Description	Default	Type
<code>camel.dataformat.json-jackson.timezone</code>	If set then Jackson will use the Timezone when marshalling/unmarshalling. This option will have no effect on the others Json DataFormat, like gson, fastjson and xstream.		String
<code>camel.dataformat.json-jackson.unmarshalling-type</code>	Class name of the java type to use when unmarshalling.		String
<code>camel.dataformat.json-jackson.use-default-object-mapper</code>	Whether to lookup and use default Jackson ObjectMapper from the registry.	true	Boolean
<code>camel.dataformat.json-jackson.use-list</code>	To unmarshal to a List of Map or a List of Pojo.	false	Boolean

CHAPTER 65. JSONPATH

Camel supports [JSONPath](#) to allow using [Expression](#) or [Predicate](#) on JSON messages.

65.1. DEPENDENCIES

When using **jsonpath** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-jsonpath-starter</artifactId>
</dependency>
```

65.2. JSONPATH OPTIONS

The JSONPath language supports 8 options, which are listed below.

Name	Default	Java Type	Description
resultType		String	Sets the class name of the result type (type from output).
suppressExceptions		Boolean	Whether to suppress exceptions such as PathNotFoundException.
allowSimple		Boolean	Whether to allow inlined Simple exceptions in the JSONPath expression.
allowEasyPredicate		Boolean	Whether to allow using the easy predicate parser to pre-parse predicates.
writeAsString		Boolean	Whether to write the output of each row/element as a JSON String value instead of a Map/POJO value.
headerName		String	Name of header to use as input, instead of the message body.

Name	Default	Java Type	Description
option		Enum	To configure additional options on JSONPath. Multiple values can be separated by comma. Enum values: • DEFAULT_PATH_LEAF_TO_NULL • ALWAYS_RETURN_LIST • AS_PATH_LIST • SUPPRESS_EXCEPTIONS • REQUIRE_PROPERTIES
trim		Boolean	Whether to trim the value to remove leading and trailing whitespaces and line breaks.

65.3. EXAMPLES

For example, you can use JSONPath in a [Predicate](#) with the [Content Based Router EIP](#) .

```
from("queue:books.new")
  .choice()
    .when().jsonpath("$.store.book[?(@.price < 10)]")
      .to("jms:queue:book.cheap")
    .when().jsonpath("$.store.book[?(@.price < 30)]")
      .to("jms:queue:book.average")
    .otherwise()
      .to("jms:queue:book.expensive");
```

And in XML DSL:

```
<route>
  <from uri="direct:start"/>
  <choice>
    <when>
      <jsonpath>$.store.book[?(@.price < 10)]</jsonpath>
      <to uri="mock:cheap"/>
    </when>
    <when>
      <jsonpath>$.store.book[?(@.price < 30)]</jsonpath>
      <to uri="mock:average"/>
    </when>
    <otherwise>
      <to uri="mock:expensive"/>
    </otherwise>
  </choice>
</route>
```

65.4. JSONPATH SYNTAX

Using the JSONPath syntax takes some time to learn, even for basic predicates. So for example to find out all the cheap books you have to do:

```
$$.store.book[?(@.price < 20)]
```

65.4.1. Easy JSONPath Syntax

However, what if you could just write it as:

```
store.book.price < 20
```

And you can omit the path if you just want to look at nodes with a price key:

```
price < 20
```

To support this there is a **EasyPredicateParser** which kicks-in if you have defined the predicate using a basic style. That means the predicate must not start with the **\$** sign, and only include one operator.

The easy syntax is:

```
left OP right
```

You can use Camel simple language in the right operator, eg:

```
store.book.price < ${header.limit}
```

See the [JSONPath](#) project page for more syntax examples.

65.5. SUPPORTED MESSAGE BODY TYPES

Camel JSonPath supports message body using the following types:

Type	Comment
File	Reading from files
String	Plain strings
Map	Message bodies as java.util.Map types
List	Message bodies as java.util.List types
POJO	Optional If Jackson is on the classpath, then camel-jsonpath is able to use Jackson to read the message body as POJO and convert to java.util.Map which is supported by JSonPath. For example, you can add camel-jackson as dependency to include Jackson.

Type	Comment
InputStream	If none of the above types matches, then Camel will attempt to read the message body as a java.io.InputStream .

If a message body is of unsupported type then an exception is thrown by default, however you can configure JXPath to suppress exceptions (see below)

65.6. SUPPRESSING EXCEPTIONS

By default, jsonpath will throw an exception if the json payload does not have a valid path accordingly to the configured jsonpath expression. In some use-cases you may want to ignore this in case the json payload contains optional data. Therefore, you can set the option **suppressExceptions** to **true** to ignore this as shown:

```
from("direct:start")
  .choice()
    // use true to suppress exceptions
    .when().jsonpath("person.middlename", true)
      .to("mock:middle")
    .otherwise()
      .to("mock:other");
```

And in XML DSL:

```
<route>
  <from uri="direct:start"/>
  <choice>
    <when>
      <jsonpath suppressExceptions="true">person.middlename</jsonpath>
      <to uri="mock:middle"/>
    </when>
    <otherwise>
      <to uri="mock:other"/>
    </otherwise>
  </choice>
</route>
```

This option is also available on the **@JsonPath** annotation.

65.7. INLINE SIMPLE EXPRESSIONS

It's possible to inlined [Simple](#) language in the JXPath expression using the simple syntax **\${xxx}**.

An example is shown below:

```
from("direct:start")
  .choice()
    .when().jsonpath("$.store.book[?(@.price < ${header.cheap})]")
      .to("mock:cheap")
```

```
.when().jsonpath("$.store.book[?(@.price < ${header.average})]")
    .to("mock:average")
    .otherwise()
    .to("mock:expensive");
```

And in XML DSL:

```
<route>
  <from uri="direct:start"/>
  <choice>
    <when>
      <jsonpath>$.store.book[?(@.price < ${header.cheap})]</jsonpath>
      <to uri="mock:cheap"/>
    </when>
    <when>
      <jsonpath>$.store.book[?(@.price < ${header.average})]</jsonpath>
      <to uri="mock:average"/>
    </when>
    <otherwise>
      <to uri="mock:expensive"/>
    </otherwise>
  </choice>
</route>
```

You can turn off support for inlined Simple expression by setting the option **allowSimple** to **false** as shown:

```
.when().jsonpath("$.store.book[?(@.price < 10)]", false, false)
```

And in XML DSL:

```
<jsonpath allowSimple="false">$.store.book[?(@.price < 10)]</jsonpath>
```

65.8. JSONPATH INJECTION

You can use [Bean Integration](#) to invoke a method on a bean and use various languages such as JSONPath (via the **@JsonPath** annotation) to extract a value from the message and bind it to a method parameter, as shown below:

```
public class Foo {

    @Consume("activemq:queue:books.new")
    public void doSomething(@JsonPath("$.store.book[*].author") String author, @Body String json) {
        // process the inbound message here
    }
}
```

65.9. ENCODING DETECTION

The encoding of the JSON document is detected automatically, if the document is encoded in unicode (UTF-8, UTF-16LE, UTF-16BE, UTF-32LE, UTF-32BE) as specified in RFC-4627. If the encoding is a non-unicode encoding, you can either make sure that you enter the document in String format to

JSONPath, or you can specify the encoding in the header **CamelJsonPathJsonEncoding** which is defined as a constant in: **JsonpathConstants.HEADER_JSON_ENCODING**.

65.10. SPLIT JSON DATA INTO SUB ROWS AS JSON

You can use JSONPath to split a JSON document, such as:

```
from("direct:start")
  .split().jsonpath("$.store.book[*]")
  .to("log:book");
```

Then each book is logged, however the message body is a **Map** instance. Sometimes you may want to output this as plain String JSON value instead, which can be done with the **writeAsString** option as shown:

```
from("direct:start")
  .split().jsonpathWriteAsString("$.store.book[*]")
  .to("log:book");
```

Then each book is logged as a String JSON value.

65.11. USING HEADER AS INPUT

By default, JSONPath uses the message body as the input source. However, you can also use a header as input by specifying the **headerName** option.

For example to count the number of books from a JSON document that was stored in a header named **books** you can do:

```
from("direct:start")
  .setHeader("numberOfBooks")
  .jsonpath("$.store.book.length()", false, int.class, "books")
  .to("mock:result");
```

In the **jsonpath** expression above we specify the name of the header as **books**, and we also told that we wanted the result to be converted as an integer by **int.class**.

The same example in XML DSL would be:

```
<route>
  <from uri="direct:start"/>
  <setHeader name="numberOfBooks">
    <jsonpath headerName="books" resultType="int">$.store.book.length()</jsonpath>
  </setHeader>
  <to uri="mock:result"/>
</route>
```

65.12. SPRING BOOT AUTO-CONFIGURATION

The component supports 8 options, which are listed below.

Name	Description	Default	Type
<code>camel.language.js onpath.allow- easy-predicate</code>	Whether to allow using the easy predicate parser to pre-parse predicates.	true	Boolean
<code>camel.language.js onpath.allow- simple</code>	Whether to allow inlined Simple exceptions in the JSONPath expression.	true	Boolean
<code>camel.language.js onpath.enabled</code>	Whether to enable auto configuration of the jsonpath language. This is enabled by default.		Boolean
<code>camel.language.js onpath.header- name</code>	Name of header to use as input, instead of the message body.		String
<code>camel.language.js onpath.option</code>	To configure additional options on JSONPath. Multiple values can be separated by comma.		String
<code>camel.language.js onpath.suppress- exceptions</code>	Whether to suppress exceptions such as PathNotFoundException.	false	Boolean
<code>camel.language.js onpath.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks.	true	Boolean
<code>camel.language.js onpath.write-as- string</code>	Whether to write the output of each row/element as a JSON String value instead of a Map/POJO value.	false	Boolean

CHAPTER 66. KAFKA

Both producer and consumer are supported

The Kafka component is used for communicating with [Apache Kafka](#) message broker.

66.1. DEPENDENCIES

When using **kafka** with Red Hat build of Camel Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>  
  <groupId>org.apache.camel.springboot</groupId>  
  <artifactId>camel-kafka-starter</artifactId>  
</dependency>
```

66.2. URI FORMAT

```
kafka:topic[?options]
```

66.3. CONFIGURING OPTIONS

Camel components are configured on two separate levels:

- component level
- endpoint level

66.3.1. Configuring Component Options

At the component level, you set general and shared configurations that are, then, inherited by the endpoints. It is the highest configuration level. For example, a component may have security settings, credentials for authentication, urls for network connection and so forth. Some components only have a few options, and others may have many. Because components typically have pre-configured defaults that are commonly used, then you may often only need to configure a few options on a component; or none at all.

You can configure components using:

- the [Component DSL](#).
- in a configuration file (application.properties, *.yaml files, etc).
- directly in the Java code.

66.3.2. Configuring Endpoint Options

You usually spend more time setting up endpoints because they have many options. These options help you customize what you want the endpoint to do. The options are also categorized into whether the endpoint is used as a consumer (from), as a producer (to), or both.

Configuring endpoints is most often done directly in the endpoint URI as path and query parameters. You can also use the [Endpoint DSL](#) and [DataFormat DSL](#) as a type safe way of configuring endpoints and data formats in Java.

A good practice when configuring options is to use [Property Placeholders](#).

Property placeholders provide a few benefits:

- They help prevent using hardcoded urls, port numbers, sensitive information, and other settings.
- They allow externalizing the configuration from the code.
- They help the code to become more flexible and reusable.

The following two sections list all the options, firstly for the component followed by the endpoint.

66.4. COMPONENT OPTIONS

The Kafka component supports 116 options, which are listed below.

Name	Description	Default	Type
additionalProperties (common)	Sets additional properties for either kafka consumer or kafka producer in case they can't be set directly on the camel configurations (e.g: new Kafka properties that are not reflected yet in Camel configurations), the properties have to be prefixed with <code>additionalProperties..</code> E.g: <code>additionalProperties.transactional.id=12345&additionalProperties.schema.registry.url=http://localhost:8811/avro.</code>		Map
brokers (common)	URL of the Kafka brokers to use. The format is <code>host1:port1,host2:port2</code> , and the list can be a subset of brokers or a VIP pointing to a subset of brokers. This option is known as <code>bootstrap.servers</code> in the Kafka documentation.		String
clientId (common)	The client id is a user-specified string sent in each request to help trace calls. It should logically identify the application making the request.		String
configuration (common)	Allows to pre-configure the Kafka component with common options that the endpoints will reuse.		KafkaConfiguration
headerFilterStrategy (common)	To use a custom HeaderFilterStrategy to filter header to and from Camel message.		HeaderFilterStrategy

Name	Description	Default	Type
reconnectBackoffMaxMs (common)	The maximum amount of time in milliseconds to wait when reconnecting to a broker that has repeatedly failed to connect. If provided, the backoff per host will increase exponentially for each consecutive connection failure, up to this maximum. After calculating the backoff increase, 20% random jitter is added to avoid connection storms.	1000	Integer
retryBackoffMaxMs (common)	The maximum amount of time in milliseconds to wait when retrying a request to the broker that has repeatedly failed. If provided, the backoff per client will increase exponentially for each failed request, up to this maximum. To prevent all clients from being synchronized upon retry, a randomized jitter with a factor of 0.2 will be applied to the backoff, resulting in the backoff falling within a range between 20% below and 20% above the computed value. If <code>retry.backoff.ms</code> is set to be higher than <code>retry.backoff.max.ms</code> , then <code>retry.backoff.max.ms</code> will be used as a constant backoff from the beginning without any exponential increase.	1000	Integer
retryBackoffMs (common)	The amount of time to wait before attempting to retry a failed request to a given topic partition. This avoids repeatedly sending requests in a tight loop under some failure scenarios. This value is the initial backoff value and will increase exponentially for each failed request, up to the <code>retry.backoff.max.ms</code> value.	100	Integer
shutdownTimeout (common)	Timeout in milliseconds to wait gracefully for the consumer or producer to shutdown and terminate its worker threads.	30000	int
allowManualCommit (consumer)	Whether to allow doing manual commits via <code>KafkaManualCommit</code> . If this option is enabled then an instance of <code>KafkaManualCommit</code> is stored on the Exchange message header, which allows end users to access this API and perform manual offset commits via the Kafka consumer.	false	boolean
autoCommitEnable (consumer)	If true, periodically commit to ZooKeeper the offset of messages already fetched by the consumer. This committed offset will be used when the process fails as the position from which the new consumer will begin.	true	Boolean
autoCommitIntervalMs (consumer)	The frequency in ms that the consumer offsets are committed to zookeeper.	5000	Integer

Name	Description	Default	Type
autoCommitOnStop (consumer)	Whether to perform an explicit auto commit when the consumer stops to ensure the broker has a commit from the last consumed message. This requires the option <code>autoCommitEnable</code> is turned on. The possible values are: <code>sync</code>, <code>async</code>, or <code>none</code>. And <code>sync</code> is the default value. Enum values: • <code>sync</code> • <code>async</code> • <code>none</code>	<code>sync</code>	String
autoOffsetReset (consumer)	What to do when there is no initial offset in ZooKeeper or if an offset is out of range: <code>earliest</code> : automatically reset the offset to the earliest offset <code>latest</code> : automatically reset the offset to the latest offset <code>fail</code>: throw exception to the consumer. Enum values: • <code>latest</code> • <code>earliest</code> • <code>none</code>	<code>latest</code>	String
batching (consumer)	Whether to use batching for processing or streaming. The default is <code>false</code>, which uses streaming.	<code>false</code>	boolean
breakOnFirstError (consumer)	This options controls what happens when a consumer is processing an exchange and it fails. If the option is <code>false</code> then the consumer continues to the next message and processes it. If the option is <code>true</code> then the consumer breaks out, and will seek back to offset of the message that caused a failure, and then re-attempt to process this message. However this can lead to endless processing of the same message if its bound to fail every time, eg a poison message. Therefore its recommended to deal with that for example by using Camel's error handler.	<code>false</code>	boolean

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
checkCrcs (consumer)	Automatically check the CRC32 of the records consumed. This ensures no on-the-wire or on-disk corruption to the messages occurred. This check adds some overhead, so it may be disabled in cases seeking extreme performance.	true	Boolean
commitTimeoutMs (consumer)	The maximum time, in milliseconds, that the code will wait for a synchronous commit to complete.	5000	Long
consumerRequestTimeoutMs (consumer)	The configuration controls the maximum amount of time the client will wait for the response of a request. If the response is not received before the timeout elapses the client will resend the request if necessary or fail the request if retries are exhausted.	40000	Integer
consumersCount (consumer)	The number of consumers that connect to kafka server. Each consumer is run on a separate thread, that retrieves and process the incoming data.	1	int
fetchMaxBytes (consumer)	The maximum amount of data the server should return for a fetch request This is not an absolute maximum, if the first message in the first non-empty partition of the fetch is larger than this value, the message will still be returned to ensure that the consumer can make progress. The maximum message size accepted by the broker is defined via <code>message.max.bytes</code> (broker config) or <code>max.message.bytes</code> (topic config). Note that the consumer performs multiple fetches in parallel.	52428800	Integer
fetchMinBytes (consumer)	The minimum amount of data the server should return for a fetch request. If insufficient data is available the request will wait for that much data to accumulate before answering the request.	1	Integer

Name	Description	Default	Type
fetchWaitMaxMs (consumer)	The maximum amount of time the server will block before answering the fetch request if there isn't sufficient data to immediately satisfy fetch.min.bytes.	500	Integer
groupId (consumer)	A string that uniquely identifies the group of consumer processes to which this consumer belongs. By setting the same group id multiple processes indicate that they are all part of the same consumer group. This option is required for consumers.		String
groupInstanceId (consumer)	A unique identifier of the consumer instance provided by the end user. Only non-empty strings are permitted. If set, the consumer is treated as a static member, which means that only one instance with this ID is allowed in the consumer group at any time. This can be used in combination with a larger session timeout to avoid group rebalances caused by transient unavailability (e.g. process restarts). If not set, the consumer will join the group as a dynamic member, which is the traditional behavior.		String
headerDeserializer (consumer)	To use a custom <code>KafkaHeaderDeserializer</code> to deserialize kafka headers values.		<code>KafkaHeaderDeserializer</code>
heartbeatIntervalMs (consumer)	The expected time between heartbeats to the consumer coordinator when using Kafka's group management facilities. Heartbeats are used to ensure that the consumer's session stays active and to facilitate rebalancing when new consumers join or leave the group. The value must be set lower than <code>session.timeout.ms</code> , but typically should be set no higher than 1/3 of that value. It can be adjusted even lower to control the expected time for normal rebalances.	3000	Integer
keyDeserializer (consumer)	Deserializer class for key that implements the <code>Deserializer</code> interface.	<code>org.apache.kafka.common.serialization.StringDeserializer</code>	String

Name	Description	Default	Type
maxPartitionFetchBytes (consumer)	The maximum amount of data per-partition the server will return. The maximum total memory used for a request will be <code>#partitions max.partition.fetch.bytes</code> . This size must be at least as large as the maximum message size the server allows or else it is possible for the producer to send messages larger than the consumer can fetch. If that happens, the consumer can get stuck trying to fetch a large message on a certain partition.	1048576	Integer
maxPollIntervalMs (consumer)	The maximum delay between invocations of <code>poll()</code> when using consumer group management. This places an upper bound on the amount of time that the consumer can be idle before fetching more records. If <code>poll()</code> is not called before expiration of this timeout, then the consumer is considered failed and the group will rebalance in order to reassign the partitions to another member.		Long
maxPollRecords (consumer)	The maximum number of records returned in a single call to <code>poll()</code> .	500	Integer
offsetRepository (consumer)	The offset repository to use in order to locally store the offset of each partition of the topic. Defining one will disable the autocommit.		StateRepository
partitionAssignor (consumer)	The class name of the partition assignment strategy that the client will use to distribute partition ownership amongst consumer instances when group management is used.	<code>org.apache.kafka.clients.consumer.RangeAssignor</code>	String

Name	Description	Default	Type
pollOnError (consumer)	What to do if kafka threw an exception while polling for new messages. Will by default use the value from the component configuration unless an explicit value has been configured on the endpoint level. DISCARD will discard the message and continue to poll next message. ERROR_HANDLER will use Camel's error handler to process the exception, and afterwards continue to poll next message. RECONNECT will re-connect the consumer and try poll the message again. RETRY will let the consumer retry polling the same message again. STOP will stop the consumer (have to be manually started/restarted if the consumer should be able to consume messages again). Enum values: ● DISCARD ● ERROR_HANDLER ● RECONNECT ● RETRY ● STOP	ERROR_HANDLER	PollOnError
pollTimeoutMs (consumer)	The timeout used when polling the KafkaConsumer.	5000	Long
preValidateHostAndPort (consumer)	Whether to eager validate that broker host:port is valid and can be DNS resolved to known host during starting this consumer. If the validation fails, then an exception is thrown, which makes Camel fail fast. Disabling this will postpone the validation after the consumer is started, and Camel will keep re-connecting in case of validation or DNS resolution error.	true	boolean
seekTo (consumer)	Set if KafkaConsumer will read from beginning or end on startup: beginning : read from beginning end : read from end This is replacing the earlier property seekToBeginning. Enum values: ● beginning ● end		String
sessionTimeoutMs (consumer)	The timeout used to detect failures when using Kafka's group management facilities.	10000	Integer

Name	Description	Default	Type
specificAvroReader (consumer)	This enables the use of a specific Avro reader for use with the Confluent Platform schema registry and the <code>io.confluent.kafka.serializers.KafkaAvroDeserializer</code> . This option is only available in the Confluent Platform (not standard Apache Kafka).	false	boolean
topicsPattern (consumer)	Whether the topic is a pattern (regular expression). This can be used to subscribe to dynamic number of topics matching the pattern.	false	boolean
valueDeserializer (consumer)	Deserializer class for value that implements the <code>Deserializer</code> interface.	<code>org.apache.kafka.common.serialization.StringDeserializer</code>	String
createConsumerBackoffInterval (consumer (advanced))	The delay in millis seconds to wait before trying again to create the kafka consumer (kafka-client).	5000	long
createConsumerBackoffMaxAttempts (consumer (advanced))	Maximum attempts to create the kafka consumer (kafka-client), before eventually giving up and failing. Error during creating the consumer may be fatal due to invalid configuration and as such recovery is not possible. However, one part of the validation is DNS resolution of the bootstrap broker hostnames. This may be a temporary networking problem, and could potentially be recoverable. While other errors are fatal, such as some invalid kafka configurations. Unfortunately, kafka-client does not separate this kind of errors. Camel will by default retry forever, and therefore never give up. If you want to give up after many attempts then set this option and Camel will then when giving up terminate the consumer. To try again, you can manually restart the consumer by stopping, and starting the route.		int

Name	Description	Default	Type
isolationLevel (consumer (advanced))	Controls how to read messages written transactionally. If set to <code>read_committed</code>, <code>consumer.poll()</code> will only return transactional messages which have been committed. If set to <code>read_uncommitted</code> (the default), <code>consumer.poll()</code> will return all messages, even transactional messages which have been aborted. Non-transactional messages will be returned unconditionally in either mode. Messages will always be returned in offset order. Hence, in <code>read_committed</code> mode, <code>consumer.poll()</code> will only return messages up to the last stable offset (LSO), which is the one less than the offset of the first open transaction. In particular, any messages appearing after messages belonging to ongoing transactions will be withheld until the relevant transaction has been completed. As a result, <code>read_committed</code> consumers will not be able to read up to the high watermark when there are in flight transactions. Further, when in <code>read_committed</code> the <code>seekToEnd</code> method will return the LSO. Enum values: • <code>read_uncommitted</code> • <code>read_committed</code>		String
kafkaManualCommitFactory (consumer (advanced))	Autowired Factory to use for creating <code>KafkaManualCommit</code> instances. This allows to plugin a custom factory to create custom <code>KafkaManualCommit</code> instances in case special logic is needed when doing manual commits that deviates from the default implementation that comes out of the box.		<code>KafkaManualCommitFactory</code>
pollExceptionStrategy (consumer (advanced))	Autowired To use a custom strategy with the consumer to control how to handle exceptions thrown from the Kafka broker while pooling messages.		<code>PollExceptionStrategy</code>
subscribeConsumerBackoffInterval (consumer (advanced))	The delay in millis seconds to wait before trying again to subscribe to the kafka broker.	5000	long

Name	Description	Default	Type
subscribeConsumerBackoffMaxAttempts (consumer (advanced))	Maximum number the kafka consumer will attempt to subscribe to the kafka broker, before eventually giving up and failing. Error during subscribing the consumer to the kafka topic could be temporary errors due to network issues, and could potentially be recoverable. Camel will by default retry forever, and therefore never give up. If you want to give up after many attempts, then set this option and Camel will then when giving up terminate the consumer. You can manually restart the consumer by stopping and starting the route, to try again.		int
batchWithIndividualHeaders (producer)	If this feature is enabled and a single element of a batch is an Exchange or Message, the producer will generate individual kafka header values for it by using the batch Message to determine the values. Normal behavior consists of always using the same header values (which are determined by the parent Exchange which contains the Iterable or Iterator).	false	boolean
bufferMemorySize (producer)	The total bytes of memory the producer can use to buffer records waiting to be sent to the server. If records are sent faster than they can be delivered to the server the producer will either block or throw an exception based on the preference specified by <code>block.on.buffer.full</code> . This setting should correspond roughly to the total memory the producer will use, but is not a hard bound since not all memory the producer uses is used for buffering. Some additional memory will be used for compression (if compression is enabled) as well as for maintaining in-flight requests.	33554432	Integer
compressionCodec (producer)	This parameter allows you to specify the compression codec for all data generated by this producer. Valid values are none, gzip and snappy. Enum values: • none • gzip • snappy • lz4	none	String
connectionMaxIdleMs (producer)	Close idle connections after the number of milliseconds specified by this config.	540000	Integer

Name	Description	Default	Type
deliveryTimeoutMs (producer)	An upper bound on the time to report success or failure after a call to send() returns. This limits the total time that a record will be delayed prior to sending, the time to await acknowledgement from the broker (if expected), and the time allowed for retrievable send failures.	120000	Integer
enableIdempotence (producer)	If set to 'true' the producer will ensure that exactly one copy of each message is written in the stream. If 'false', producer retries may write duplicates of the retried message in the stream. If set to true this option will require max.in.flight.requests.per.connection to be set to 1 and retries cannot be zero and additionally acks must be set to 'all'.	false	boolean
headerSerializer (producer)	To use a custom KafkaHeaderSerializer to serialize kafka headers values.		KafkaHeaderSerializer
key (producer)	The record key (or null if no key is specified). If this option has been configured then it take precedence over header KafkaConstants#KEY.		String
keySerializer (producer)	The serializer class for keys (defaults to the same as for messages if nothing is given).	org.apache.kafka.common.serialization.StringSerializer	String
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

Name	Description	Default	Type
lingerMs (producer)	The producer groups together any records that arrive in between request transmissions into a single batched request. Normally this occurs only under load when records arrive faster than they can be sent out. However in some circumstances the client may want to reduce the number of requests even under moderate load. This setting accomplishes this by adding a small amount of artificial delay that is, rather than immediately sending out a record the producer will wait for up to the given delay to allow other records to be sent so that the sends can be batched together. This can be thought of as analogous to Nagle's algorithm in TCP. This setting gives the upper bound on the delay for batching: once we get batch.size worth of records for a partition it will be sent immediately regardless of this setting, however if we have fewer than this many bytes accumulated for this partition we will 'linger' for the specified time waiting for more records to show up. This setting defaults to 0 (i.e. no delay). Setting <code>linger.ms=5</code> , for example, would have the effect of reducing the number of requests sent but would add up to 5ms of latency to records sent in the absense of load.	0	Integer
maxBlockMs (producer)	The configuration controls how long sending to kafka will block. These methods can be blocked for multiple reasons. For e.g: buffer full, metadata unavailable. This configuration imposes maximum limit on the total time spent in fetching metadata, serialization of key and value, partitioning and allocation of buffer memory when doing a <code>send()</code> . In case of <code>partitionsFor()</code> , this configuration imposes a maximum time threshold on waiting for metadata.	60000	Integer
maxInFlightRequest (producer)	The maximum number of unacknowledged requests the client will send on a single connection before blocking. Note that if this setting is set to be greater than 1 and there are failed sends, there is a risk of message re-ordering due to retries (i.e., if retries are enabled).	5	Integer
maxRequestSize (producer)	The maximum size of a request. This is also effectively a cap on the maximum record size. Note that the server has its own cap on record size which may be different from this. This setting will limit the number of record batches the producer will send in a single request to avoid sending huge requests.	1048576	Integer

Name	Description	Default	Type
metadataMaxAgeMs (producer)	The period of time in milliseconds after which we force a refresh of metadata even if we haven't seen any partition leadership changes to proactively discover any new brokers or partitions.	300000	Integer
metricReporters (producer)	A list of classes to use as metrics reporters. Implementing the MetricReporter interface allows plugging in classes that will be notified of new metric creation. The JmxReporter is always included to register JMX statistics.		String
metricsSampleWindowMs (producer)	The number of samples maintained to compute metrics.	30000	Integer
noOfMetricsSample (producer)	The number of samples maintained to compute metrics.	2	Integer
partitioner (producer)	The partitioner class for partitioning messages amongst sub-topics. The default partitioner is based on the hash of the key.	org.apache.kafka.clients.producer.internals.DefaultPartitioner	String
partitionerIgnoreKeys (producer)	Whether the message keys should be ignored when computing the partition. This setting has effect only when partitioner is not set.	false	boolean
partitionKey (producer)	The partition to which the record will be sent (or null if no partition was specified). If this option has been configured then it take precedence over header <code>KafkaConstants#PARTITION_KEY</code> .		Integer

Name	Description	Default	Type
producerBatchSize (producer)	The producer will attempt to batch records together into fewer requests whenever multiple records are being sent to the same partition. This helps performance on both the client and the server. This configuration controls the default batch size in bytes. No attempt will be made to batch records larger than this size. Requests sent to brokers will contain multiple batches, one for each partition with data available to be sent. A small batch size will make batching less common and may reduce throughput (a batch size of zero will disable batching entirely). A very large batch size may use memory a bit more wastefully as we will always allocate a buffer of the specified batch size in anticipation of additional records.	16384	Integer
queueBufferingMaxMessages (producer)	The maximum number of unsent messages that can be queued up the producer when using async mode before either the producer must be blocked or data must be dropped.	10000	Integer
receiveBufferBytes (producer)	The size of the TCP receive buffer (SO_RCVBUF) to use when reading data.	65536	Integer
reconnectBackoffMs (producer)	The amount of time to wait before attempting to reconnect to a given host. This avoids repeatedly connecting to a host in a tight loop. This backoff applies to all requests sent by the consumer to the broker.	50	Integer
recordMetadata (producer)	Whether the producer should store the RecordMetadata results from sending to Kafka. The results are stored in a List containing the RecordMetadata metadata's. The list is stored on a header with the key <code>KafkaConstants#KAFKA_RECORDMETA</code> .	true	boolean

Name	Description	Default	Type
requestRequiredAcks (producer)	The number of acknowledgments the producer requires the leader to have received before considering a request complete. This controls the durability of records that are sent. The following settings are common: <code>acks=0</code> If set to zero then the producer will not wait for any acknowledgment from the server at all. The record will be immediately added to the socket buffer and considered sent. No guarantee can be made that the server has received the record in this case, and the retries configuration will not take effect (as the client won't generally know of any failures). The offset given back for each record will always be set to <code>-1</code>. <code>acks=1</code> This will mean the leader will write the record to its local log but will respond without awaiting full acknowledgement from all followers. In this case should the leader fail immediately after acknowledging the record but before the followers have replicated it then the record will be lost. <code>acks=all</code> This means the leader will wait for the full set of in-sync replicas to acknowledge the record. This guarantees that the record will not be lost as long as at least one in-sync replica remains alive. This is the strongest available guarantee. Enum values: • <code>-1</code> • <code>0</code> • <code>1</code> • <code>all</code>	1	String
requestTimeoutMs (producer)	The amount of time the broker will wait trying to meet the <code>request.required.acks</code> requirement before sending back an error to the client.	30000	Integer
retries (producer)	Setting a value greater than zero will cause the client to resend any record whose send fails with a potentially transient error. Note that this retry is no different than if the client resent the record upon receiving the error. Allowing retries will potentially change the ordering of records because if two records are sent to a single partition, and the first fails and is retried but the second succeeds, then the second record may appear first.	0	Integer

Name	Description	Default	Type
retryBackoffMs (producer)	Before each retry, the producer refreshes the metadata of relevant topics to see if a new leader has been elected. Since leader election takes a bit of time, this property specifies the amount of time that the producer waits before refreshing the metadata.	100	Integer
sendBufferBytes (producer)	Socket write buffer size.	131072	Integer
useIterator (producer)	Sets whether sending to kafka should send the message body as a single record, or use a <code>java.util.Iterator</code> to send multiple records to kafka (if the message body can be iterated).	true	boolean
valueSerializer (producer)	The serializer class for messages.	<code>org.apache.kafka.common.serialization.StringSerializer</code>	String
workerPool (producer)	To use a custom worker pool for continue routing Exchange after kafka server has acknowledge the message that was sent to it from <code>KafkaProducer</code> using asynchronous non-blocking processing. If using this option then you must handle the lifecycle of the thread pool to shut the pool down when no longer needed.		<code>ExecutorService</code>
workerPoolCoreSize (producer)	Number of core threads for the worker pool for continue routing Exchange after kafka server has acknowledge the message that was sent to it from <code>KafkaProducer</code> using asynchronous non-blocking processing.	10	Integer
workerPoolMaxSize (producer)	Maximum number of threads for the worker pool for continue routing Exchange after kafka server has acknowledge the message that was sent to it from <code>KafkaProducer</code> using asynchronous non-blocking processing.	20	Integer

Name	Description	Default	Type
autowiredEnabled (advanced)	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	boolean
kafkaClientFactory (advanced)	Autowired Factory to use for creating org.apache.kafka.clients.consumer.KafkaConsumer and org.apache.kafka.clients.producer.KafkaProducer instances. This allows to configure a custom factory to create instances with logic that extends the vanilla Kafka clients.		KafkaClientFactory
synchronous (advanced)	Sets whether synchronous processing should be strictly used.	false	boolean
healthCheckConsumerEnabled (health)	Used for enabling or disabling all consumer based health checks from this component.	true	boolean
healthCheckProducerEnabled (health)	Used for enabling or disabling all producer based health checks from this component. Notice: Camel has by default disabled all producer based health-checks. You can turn on producer checks globally by setting camel.health.producersEnabled=true.	true	boolean
interceptorClasses (monitoring)	Sets interceptors for producer or consumers. Producer interceptors have to be classes implementing org.apache.kafka.clients.producer.ProducerInterceptor or Consumer interceptors have to be classes implementing org.apache.kafka.clients.consumer.ConsumerInterceptor. Note that if you use Producer interceptor on a consumer it will throw a class cast exception in runtime.		String
schemaRegistryURL (confluent)	URL of the Confluent Platform schema registry servers to use. The format is host1:port1,host2:port2. This is known as schema.registry.url in the Confluent Platform documentation. This option is only available in the Confluent Platform (not standard Apache Kafka).		String
kerberosBeforeReloginMinTime (security)	Login thread sleep time between refresh attempts.	60000	Integer

Name	Description	Default	Type
kerberosInitCmd (security)	Kerberos kinit command path. Default is /usr/bin/kinit.	/usr/bin/kinit	String
kerberosPrincipalToLocalRules (security)	A list of rules for mapping from principal names to short names (typically operating system usernames). The rules are evaluated in order and the first rule that matches a principal name is used to map it to a short name. Any later rules in the list are ignored. By default, principal names of the form {username}/{hostname}{REALM} are mapped to {username}. For more details on the format please see the security authorization and acls documentation.. Multiple values can be separated by comma.	DEFAULT	String
kerberosRenewJitter (security)	Percentage of random jitter added to the renewal time.	0.05	Double
kerberosRenewWindowFactor (security)	Login thread will sleep until the specified window factor of time from last refresh to ticket's expiry has been reached, at which time it will try to renew the ticket.	0.8	Double
saslJaasConfig (security)	Expose the kafka sasl.jaas.config parameter Example: org.apache.kafka.common.security.plain.PlainLoginModule required username=USERNAME password=PASSWORD;.		String
saslKerberosServiceName (security)	The Kerberos principal name that Kafka runs as. This can be defined either in Kafka's JAAS config or in Kafka's config.		String
saslMechanism (security)	The Simple Authentication and Security Layer (SASL) Mechanism used. For the valid values see .	GSSAPI	String
securityProtocol (security)	Protocol used to communicate with brokers. SASL_PLAINTEXT, PLAINTEXT and SSL are supported.	PLAINTEXT	String
sslCipherSuites (security)	A list of cipher suites. This is a named combination of authentication, encryption, MAC and key exchange algorithm used to negotiate the security settings for a network connection using TLS or SSL network protocol.By default all the available cipher suites are supported.		String

Name	Description	Default	Type
sslContextParameters (security)	SSL configuration using a Camel SSLContextParameters object. If configured it's applied before the other SSL endpoint parameters. NOTE: Kafka only supports loading keystore from file locations, so prefix the location with file: in the KeyStoreParameters.resource option.		SSLContextParameters
sslEnabledProtocols (security)	The list of protocols enabled for SSL connections. TLSv1.2, TLSv1.1 and TLSv1 are enabled by default.		String
sslEndpointAlgorithm (security)	The endpoint identification algorithm to validate server hostname using server certificate.	https	String
sslKeymanagerAlgorithm (security)	The algorithm used by key manager factory for SSL connections. Default value is the key manager factory algorithm configured for the Java Virtual Machine.	SunX509	String
sslKeyPassword (security)	The password of the private key in the key store file. This is optional for client.		String
sslKeystoreLocation (security)	The location of the key store file. This is optional for client and can be used for two-way authentication for client.		String
sslKeystorePassword (security)	The store password for the key store file. This is optional for client and only needed if ssl.keystore.location is configured.		String
sslKeystoreType (security)	The file format of the key store file. This is optional for client. Default value is JKS.	JKS	String
sslProtocol (security)	The SSL protocol used to generate the SSLContext. Default setting is TLS, which is fine for most cases. Allowed values in recent JVMs are TLS, TLSv1.1 and TLSv1.2. SSL, SSLv2 and SSLv3 may be supported in older JVMs, but their usage is discouraged due to known security vulnerabilities.		String
sslProvider (security)	The name of the security provider used for SSL connections. Default value is the default security provider of the JVM.		String
sslTrustmanagerAlgorithm (security)	The algorithm used by trust manager factory for SSL connections. Default value is the trust manager factory algorithm configured for the Java Virtual Machine.	PKIX	String

Name	Description	Default	Type
sslTruststoreLocation (security)	The location of the trust store file.		String
sslTruststorePassword (security)	The password for the trust store file.		String
sslTruststoreType (security)	The file format of the trust store file. Default value is JKS.	JKS	String
useGlobalSslContextParameters (security)	Enable usage of global SSL context parameters.	false	boolean

66.5. ENDPOINT OPTIONS

The Kafka endpoint is configured using URI syntax:

```
kafka:topic
```

with the following path and query parameters:

66.5.1. Path Parameters (1 parameters)

Name	Description	Default	Type
topic (common)	Required Name of the topic to use. On the consumer you can use comma to separate multiple topics. A producer can only send a message to a single topic.		String

66.5.2. Query Parameters (108 parameters)

Name	Description	Default	Type
additionalProperties (common)	Sets additional properties for either kafka consumer or kafka producer in case they can't be set directly on the camel configurations (e.g: new Kafka properties that are not reflected yet in Camel configurations), the properties have to be prefixed with <code>additionalProperties.</code> . E.g: <code>additionalProperties.transactional.id=12345&additionalProperties.schema.registry.url=http://localhost:8811/avro.</code>		Map

Name	Description	Default	Type
brokers (common)	URL of the Kafka brokers to use. The format is host1:port1,host2:port2, and the list can be a subset of brokers or a VIP pointing to a subset of brokers. This option is known as bootstrap.servers in the Kafka documentation.		String
clientId (common)	The client id is a user-specified string sent in each request to help trace calls. It should logically identify the application making the request.		String
headerFilterStrategy (common)	To use a custom HeaderFilterStrategy to filter header to and from Camel message.		HeaderFilterStrategy
reconnectBackoffMaxMs (common)	The maximum amount of time in milliseconds to wait when reconnecting to a broker that has repeatedly failed to connect. If provided, the backoff per host will increase exponentially for each consecutive connection failure, up to this maximum. After calculating the backoff increase, 20% random jitter is added to avoid connection storms.	1000	Integer
shutdownTimeout (common)	Timeout in milliseconds to wait gracefully for the consumer or producer to shutdown and terminate its worker threads.	30000	int
allowManualCommit (consumer)	Whether to allow doing manual commits via KafkaManualCommit. If this option is enabled then an instance of KafkaManualCommit is stored on the Exchange message header, which allows end users to access this API and perform manual offset commits via the Kafka consumer.	false	boolean
autoCommitEnable (consumer)	If true, periodically commit to ZooKeeper the offset of messages already fetched by the consumer. This committed offset will be used when the process fails as the position from which the new consumer will begin.	true	Boolean
autoCommitIntervalMs (consumer)	The frequency in ms that the consumer offsets are committed to zookeeper.	5000	Integer

Name	Description	Default	Type
autoCommitOnStop (consumer)	Whether to perform an explicit auto commit when the consumer stops to ensure the broker has a commit from the last consumed message. This requires the option <code>autoCommitEnable</code> is turned on. The possible values are: <code>sync</code>, <code>async</code>, or <code>none</code>. And <code>sync</code> is the default value. Enum values: • <code>sync</code> • <code>async</code> • <code>none</code>	<code>sync</code>	String
autoOffsetReset (consumer)	What to do when there is no initial offset in ZooKeeper or if an offset is out of range: <code>earliest</code> : automatically reset the offset to the earliest offset <code>latest</code> : automatically reset the offset to the latest offset <code>fail</code>: throw exception to the consumer. Enum values: • <code>latest</code> • <code>earliest</code> • <code>none</code>	<code>latest</code>	String
batching (consumer)	Whether to use batching for processing or streaming. The default is <code>false</code> , which uses streaming.	<code>false</code>	boolean
breakOnFirstError (consumer)	This options controls what happens when a consumer is processing an exchange and it fails. If the option is <code>false</code> then the consumer continues to the next message and processes it. If the option is <code>true</code> then the consumer breaks out, and will seek back to offset of the message that caused a failure, and then re-attempt to process this message. However this can lead to endless processing of the same message if its bound to fail every time, eg a poison message. Therefore its recommended to deal with that for example by using Camel's error handler.	<code>false</code>	boolean

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
checkCrcs (consumer)	Automatically check the CRC32 of the records consumed. This ensures no on-the-wire or on-disk corruption to the messages occurred. This check adds some overhead, so it may be disabled in cases seeking extreme performance.	true	Boolean
commitTimeoutMs (consumer)	The maximum time, in milliseconds, that the code will wait for a synchronous commit to complete.	5000	Long
consumerRequestTimeoutMs (consumer)	The configuration controls the maximum amount of time the client will wait for the response of a request. If the response is not received before the timeout elapses the client will resend the request if necessary or fail the request if retries are exhausted.	40000	Integer
consumersCount (consumer)	The number of consumers that connect to kafka server. Each consumer is run on a separate thread, that retrieves and process the incoming data.	1	int
fetchMaxBytes (consumer)	The maximum amount of data the server should return for a fetch request This is not an absolute maximum, if the first message in the first non-empty partition of the fetch is larger than this value, the message will still be returned to ensure that the consumer can make progress. The maximum message size accepted by the broker is defined via <code>message.max.bytes</code> (broker config) or <code>max.message.bytes</code> (topic config). Note that the consumer performs multiple fetches in parallel.	52428800	Integer
fetchMinBytes (consumer)	The minimum amount of data the server should return for a fetch request. If insufficient data is available the request will wait for that much data to accumulate before answering the request.	1	Integer
fetchWaitMaxMs (consumer)	The maximum amount of time the server will block before answering the fetch request if there isn't sufficient data to immediately satisfy <code>fetch.min.bytes</code> .	500	Integer

Name	Description	Default	Type
groupId (consumer)	A string that uniquely identifies the group of consumer processes to which this consumer belongs. By setting the same group id multiple processes indicate that they are all part of the same consumer group. This option is required for consumers.		String
groupId (consumer)	A unique identifier of the consumer instance provided by the end user. Only non-empty strings are permitted. If set, the consumer is treated as a static member, which means that only one instance with this ID is allowed in the consumer group at any time. This can be used in combination with a larger session timeout to avoid group rebalances caused by transient unavailability (e.g. process restarts). If not set, the consumer will join the group as a dynamic member, which is the traditional behavior.		String
headerDeserializer (consumer)	To use a custom <code>KafkaHeaderDeserializer</code> to deserialize kafka headers values.		<code>KafkaHeaderDeserializer</code>
heartbeatIntervalMs (consumer)	The expected time between heartbeats to the consumer coordinator when using Kafka's group management facilities. Heartbeats are used to ensure that the consumer's session stays active and to facilitate rebalancing when new consumers join or leave the group. The value must be set lower than <code>session.timeout.ms</code> , but typically should be set no higher than 1/3 of that value. It can be adjusted even lower to control the expected time for normal rebalances.	3000	Integer
keyDeserializer (consumer)	Deserializer class for key that implements the <code>Deserializer</code> interface.	<code>org.apache.kafka.common.serialization.StringDeserializer</code>	String

Name	Description	Default	Type
maxPartitionFetchBytes (consumer)	The maximum amount of data per-partition the server will return. The maximum total memory used for a request will be <code>#partitions max.partition.fetch.bytes</code> . This size must be at least as large as the maximum message size the server allows or else it is possible for the producer to send messages larger than the consumer can fetch. If that happens, the consumer can get stuck trying to fetch a large message on a certain partition.	1048576	Integer
maxPollIntervalMs (consumer)	The maximum delay between invocations of <code>poll()</code> when using consumer group management. This places an upper bound on the amount of time that the consumer can be idle before fetching more records. If <code>poll()</code> is not called before expiration of this timeout, then the consumer is considered failed and the group will rebalance in order to reassign the partitions to another member.		Long
maxPollRecords (consumer)	The maximum number of records returned in a single call to <code>poll()</code> .	500	Integer
offsetRepository (consumer)	The offset repository to use in order to locally store the offset of each partition of the topic. Defining one will disable the autocommit.		StateRepository
partitionAssignor (consumer)	The class name of the partition assignment strategy that the client will use to distribute partition ownership amongst consumer instances when group management is used.	org.apache.kafka.clients.consumer.RangeAssignor	String

Name	Description	Default	Type
pollOnError (consumer)	What to do if kafka threw an exception while polling for new messages. Will by default use the value from the component configuration unless an explicit value has been configured on the endpoint level. DISCARD will discard the message and continue to poll next message. ERROR_HANDLER will use Camel's error handler to process the exception, and afterwards continue to poll next message. RECONNECT will reconnect the consumer and try poll the message again. RETRY will let the consumer retry polling the same message again. STOP will stop the consumer (have to be manually started/restarted if the consumer should be able to consume messages again). Enum values: ● DISCARD ● ERROR_HANDLER ● RECONNECT ● RETRY ● STOP	ERROR_HANDLER	PollOnError
pollTimeoutMs (consumer)	The timeout used when polling the KafkaConsumer.	5000	Long
preValidateHostAndPort (consumer)	Whether to eager validate that broker host:port is valid and can be DNS resolved to known host during starting this consumer. If the validation fails, then an exception is thrown, which makes Camel fail fast. Disabling this will postpone the validation after the consumer is started, and Camel will keep reconnecting in case of validation or DNS resolution error.	true	boolean
resumeStrategy (consumer)	This option allows the user to set a custom resume strategy. The resume strategy is executed when partitions are assigned (i.e.: when connecting or reconnecting). It allows implementations to customize how to resume operations and serve as more flexible alternative to the seekTo and the offsetRepository mechanisms. See the KafkaConsumerResumeStrategy for implementation details. This option does not affect the auto commit setting. It is likely that implementations using this setting will also want to evaluate using the manual commit option along with this.		KafkaConsumerResumeStrategy

Name	Description	Default	Type
seekTo (consumer)	Set if KafkaConsumer will read from beginning or end on startup: beginning : read from beginning end : read from end This is replacing the earlier property seekToBeginning. Enum values: - beginning - end		String
sessionTimeoutMs (consumer)	The timeout used to detect failures when using Kafka's group management facilities.	10000	Integer
specificAvroReader (consumer)	This enables the use of a specific Avro reader for use with the Confluent Platform schema registry and the io.confluent.kafka.serializers.KafkaAvroDeserializer. This option is only available in the Confluent Platform (not standard Apache Kafka).	false	boolean
topicsPattern (consumer)	Whether the topic is a pattern (regular expression). This can be used to subscribe to dynamic number of topics matching the pattern.	false	boolean
valueDeserializer (consumer)	Deserializer class for value that implements the Deserializer interface.	org.apache.kafka.common.serialization.StringDeserializer	String
exceptionHandler (consumer (advanced))	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler

Name	Description	Default	Type
exchangePattern (consumer (advanced))	Sets the exchange pattern when the consumer creates an exchange. Enum values: ● InOnly ● InOut ● InOptionalOut		ExchangePattern
isolationLevel (consumer (advanced))	Controls how to read messages written transactionally. If set to <code>read_committed</code>, <code>consumer.poll()</code> will only return transactional messages which have been committed. If set to <code>read_uncommitted</code> (the default), <code>consumer.poll()</code> will return all messages, even transactional messages which have been aborted. Non-transactional messages will be returned unconditionally in either mode. Messages will always be returned in offset order. Hence, in <code>read_committed</code> mode, <code>consumer.poll()</code> will only return messages up to the last stable offset (LSO), which is the one less than the offset of the first open transaction. In particular, any messages appearing after messages belonging to ongoing transactions will be withheld until the relevant transaction has been completed. As a result, <code>read_committed</code> consumers will not be able to read up to the high watermark when there are in flight transactions. Further, when in <code>read_committed</code> the <code>seekToEnd</code> method will return the LSO. Enum values: ● <code>read_uncommitted</code> ● <code>read_committed</code>		String
kafkaManualCommitFactory (consumer (advanced))	Factory to use for creating <code>KafkaManualCommit</code> instances. This allows to plugin a custom factory to create custom <code>KafkaManualCommit</code> instances in case special logic is needed when doing manual commits that deviates from the default implementation that comes out of the box.		KafkaManualCommitFactory

Name	Description	Default	Type
batchWithIndividualHeaders (producer)	If this feature is enabled and a single element of a batch is an Exchange or Message, the producer will generate individual kafka header values for it by using the batch Message to determine the values. Normal behavior consists of always using the same header values (which are determined by the parent Exchange which contains the Iterable or Iterator).	false	boolean
bufferMemorySize (producer)	The total bytes of memory the producer can use to buffer records waiting to be sent to the server. If records are sent faster than they can be delivered to the server the producer will either block or throw an exception based on the preference specified by <code>block.on.buffer.full</code> . This setting should correspond roughly to the total memory the producer will use, but is not a hard bound since not all memory the producer uses is used for buffering. Some additional memory will be used for compression (if compression is enabled) as well as for maintaining in-flight requests.	33554432	Integer
compressionCodec (producer)	This parameter allows you to specify the compression codec for all data generated by this producer. Valid values are none, gzip and snappy. Enum values: • none • gzip • snappy • lz4	none	String
connectionMaxIdleMs (producer)	Close idle connections after the number of milliseconds specified by this config.	540000	Integer
deliveryTimeoutMs (producer)	An upper bound on the time to report success or failure after a call to <code>send()</code> returns. This limits the total time that a record will be delayed prior to sending, the time to await acknowledgement from the broker (if expected), and the time allowed for retrievable send failures.	120000	Integer

Name	Description	Default	Type
enableIdempotence (producer)	If set to 'true' the producer will ensure that exactly one copy of each message is written in the stream. If 'false', producer retries may write duplicates of the retried message in the stream. If set to true this option will require <code>max.in.flight.requests.per.connection</code> to be set to 1 and retries cannot be zero and additionally acks must be set to 'all'.	false	boolean
headerSerializer (producer)	To use a custom <code>KafkaHeaderSerializer</code> to serialize kafka headers values.		<code>KafkaHeaderSerializer</code>
key (producer)	The record key (or null if no key is specified). If this option has been configured then it take precedence over header <code>KafkaConstants#KEY</code> .		String
keySerializer (producer)	The serializer class for keys (defaults to the same as for messages if nothing is given).	<code>org.apache.kafka.common.serialization.StringSerializer</code>	String
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow <code>CamelContext</code> and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

Name	Description	Default	Type
lingerMs (producer)	The producer groups together any records that arrive in between request transmissions into a single batched request. Normally this occurs only under load when records arrive faster than they can be sent out. However in some circumstances the client may want to reduce the number of requests even under moderate load. This setting accomplishes this by adding a small amount of artificial delay that is, rather than immediately sending out a record the producer will wait for up to the given delay to allow other records to be sent so that the sends can be batched together. This can be thought of as analogous to Nagle's algorithm in TCP. This setting gives the upper bound on the delay for batching: once we get batch.size worth of records for a partition it will be sent immediately regardless of this setting, however if we have fewer than this many bytes accumulated for this partition we will 'linger' for the specified time waiting for more records to show up. This setting defaults to 0 (i.e. no delay). Setting linger.ms=5, for example, would have the effect of reducing the number of requests sent but would add up to 5ms of latency to records sent in the absense of load.	0	Integer
maxBlockMs (producer)	The configuration controls how long sending to kafka will block. These methods can be blocked for multiple reasons. For e.g: buffer full, metadata unavailable.This configuration imposes maximum limit on the total time spent in fetching metadata, serialization of key and value, partitioning and allocation of buffer memory when doing a send(). In case of partitionsFor(), this configuration imposes a maximum time threshold on waiting for metadata.	60000	Integer
maxInFlightRequest (producer)	The maximum number of unacknowledged requests the client will send on a single connection before blocking. Note that if this setting is set to be greater than 1 and there are failed sends, there is a risk of message re-ordering due to retries (i.e., if retries are enabled).	5	Integer
maxRequestSize (producer)	The maximum size of a request. This is also effectively a cap on the maximum record size. Note that the server has its own cap on record size which may be different from this. This setting will limit the number of record batches the producer will send in a single request to avoid sending huge requests.	1048576	Integer

Name	Description	Default	Type
metadataMaxAgeMs (producer)	The period of time in milliseconds after which we force a refresh of metadata even if we haven't seen any partition leadership changes to proactively discover any new brokers or partitions.	300000	Integer
metricReporters (producer)	A list of classes to use as metrics reporters. Implementing the MetricReporter interface allows plugging in classes that will be notified of new metric creation. The JmxReporter is always included to register JMX statistics.		String
metricsSampleWindowMs (producer)	The number of samples maintained to compute metrics.	30000	Integer
noOfMetricsSample (producer)	The number of samples maintained to compute metrics.	2	Integer
partitioner (producer)	The partitioner class for partitioning messages amongst sub-topics. The default partitioner is based on the hash of the key.	org.apache.kafka.clients.producer.internals.DefaultPartitioner	String
partitionKey (producer)	The partition to which the record will be sent (or null if no partition was specified). If this option has been configured then it take precedence over header <code>KafkaConstants#PARTITION_KEY</code> .		Integer
producerBatchSize (producer)	The producer will attempt to batch records together into fewer requests whenever multiple records are being sent to the same partition. This helps performance on both the client and the server. This configuration controls the default batch size in bytes. No attempt will be made to batch records larger than this size. Requests sent to brokers will contain multiple batches, one for each partition with data available to be sent. A small batch size will make batching less common and may reduce throughput (a batch size of zero will disable batching entirely). A very large batch size may use memory a bit more wastefully as we will always allocate a buffer of the specified batch size in anticipation of additional records.	16384	Integer

Name	Description	Default	Type
queueBufferingMaxMessages (producer)	The maximum number of unsent messages that can be queued up the producer when using async mode before either the producer must be blocked or data must be dropped.	10000	Integer
receiveBufferSize (producer)	The size of the TCP receive buffer (SO_RCVBUF) to use when reading data.	65536	Integer
reconnectBackoffMs (producer)	The amount of time to wait before attempting to reconnect to a given host. This avoids repeatedly connecting to a host in a tight loop. This backoff applies to all requests sent by the consumer to the broker.	50	Integer
recordMetadata (producer)	Whether the producer should store the RecordMetadata results from sending to Kafka. The results are stored in a List containing the RecordMetadata metadata's. The list is stored on a header with the key <code>KafkaConstants#KAFKA_RECORDMETA</code> .	true	boolean

Name	Description	Default	Type
requestRequiredAcks (producer)	The number of acknowledgments the producer requires the leader to have received before considering a request complete. This controls the durability of records that are sent. The following settings are common: <code>acks=0</code> If set to zero then the producer will not wait for any acknowledgment from the server at all. The record will be immediately added to the socket buffer and considered sent. No guarantee can be made that the server has received the record in this case, and the retries configuration will not take effect (as the client won't generally know of any failures). The offset given back for each record will always be set to <code>-1</code>. <code>acks=1</code> This will mean the leader will write the record to its local log but will respond without awaiting full acknowledgement from all followers. In this case should the leader fail immediately after acknowledging the record but before the followers have replicated it then the record will be lost. <code>acks=all</code> This means the leader will wait for the full set of in-sync replicas to acknowledge the record. This guarantees that the record will not be lost as long as at least one in-sync replica remains alive. This is the strongest available guarantee. Enum values: • <code>-1</code> • <code>0</code> • <code>1</code> • <code>all</code>	1	String
requestTimeoutMs (producer)	The amount of time the broker will wait trying to meet the <code>request.required.acks</code> requirement before sending back an error to the client.	30000	Integer
retries (producer)	Setting a value greater than zero will cause the client to resend any record whose send fails with a potentially transient error. Note that this retry is no different than if the client resent the record upon receiving the error. Allowing retries will potentially change the ordering of records because if two records are sent to a single partition, and the first fails and is retried but the second succeeds, then the second record may appear first.	0	Integer

Name	Description	Default	Type
retryBackoffMs (producer)	Before each retry, the producer refreshes the metadata of relevant topics to see if a new leader has been elected. Since leader election takes a bit of time, this property specifies the amount of time that the producer waits before refreshing the metadata.	100	Integer
sendBufferBytes (producer)	Socket write buffer size.	131072	Integer
valueSerializer (producer)	The serializer class for messages.	org.apache.kafka.common.serialization.StringSerializer	String
workerPool (producer)	To use a custom worker pool for continue routing Exchange after kafka server has acknowledge the message that was sent to it from KafkaProducer using asynchronous non-blocking processing. If using this option then you must handle the lifecycle of the thread pool to shut the pool down when no longer needed.		ExecutorService
workerPoolCoreSize (producer)	Number of core threads for the worker pool for continue routing Exchange after kafka server has acknowledge the message that was sent to it from KafkaProducer using asynchronous non-blocking processing.	10	Integer
workerPoolMaxSize (producer)	Maximum number of threads for the worker pool for continue routing Exchange after kafka server has acknowledge the message that was sent to it from KafkaProducer using asynchronous non-blocking processing.	20	Integer
kafkaClientFactory (advanced)	Factory to use for creating org.apache.kafka.clients.consumer.KafkaConsumer and org.apache.kafka.clients.producer.KafkaProducer instances. This allows to configure a custom factory to create instances with logic that extends the vanilla Kafka clients.		KafkaClientFactory
synchronous (advanced)	Sets whether synchronous processing should be strictly used.	false	boolean

Name	Description	Default	Type
schemaRegistryURL (confluent)	URL of the Confluent Platform schema registry servers to use. The format is host1:port1,host2:port2. This is known as schema.registry.url in the Confluent Platform documentation. This option is only available in the Confluent Platform (not standard Apache Kafka).		String
interceptorClasses (monitoring)	Sets interceptors for producer or consumers. Producer interceptors have to be classes implementing <code>org.apache.kafka.clients.producer.ProducerInterceptor</code> or Consumer interceptors have to be classes implementing <code>org.apache.kafka.clients.consumer.ConsumerInterceptor</code> . Note that if you use Producer interceptor on a consumer it will throw a class cast exception in runtime.		String
kerberosBeforeRefreshMinTime (security)	Login thread sleep time between refresh attempts.	60000	Integer
kerberosInitCmd (security)	Kerberos kinit command path. Default is <code>/usr/bin/kinit</code> .	<code>/usr/bin/kinit</code>	String
kerberosPrincipalToLocalRules (security)	A list of rules for mapping from principal names to short names (typically operating system usernames). The rules are evaluated in order and the first rule that matches a principal name is used to map it to a short name. Any later rules in the list are ignored. By default, principal names of the form <code>{username}/{hostname}{REALM}</code> are mapped to <code>{username}</code> . For more details on the format please see the security authorization and acls documentation.. Multiple values can be separated by comma.	DEFAULT	String
kerberosRenewJitter (security)	Percentage of random jitter added to the renewal time.	0.05	Double
kerberosRenewWindowFactor (security)	Login thread will sleep until the specified window factor of time from last refresh to ticket's expiry has been reached, at which time it will try to renew the ticket.	0.8	Double
saslJaasConfig (security)	Expose the kafka sasl.jaas.config parameter Example: <code>org.apache.kafka.common.security.plain.PlainLoginModule required username=USERNAME password=PASSWORD;</code> .		String

Name	Description	Default	Type
saslKerberosServiceName (security)	The Kerberos principal name that Kafka runs as. This can be defined either in Kafka's JAAS config or in Kafka's config.		String
saslMechanism (security)	The Simple Authentication and Security Layer (SASL) Mechanism used. For the valid values see .	GSSAPI	String
securityProtocol (security)	Protocol used to communicate with brokers. SASL_PLAINTEXT, PLAINTEXT and SSL are supported.	PLAINTEXT	String
sslCipherSuites (security)	A list of cipher suites. This is a named combination of authentication, encryption, MAC and key exchange algorithm used to negotiate the security settings for a network connection using TLS or SSL network protocol. By default all the available cipher suites are supported.		String
sslContextParameters (security)	SSL configuration using a Camel SSLContextParameters object. If configured it's applied before the other SSL endpoint parameters. NOTE: Kafka only supports loading keystore from file locations, so prefix the location with file: in the KeyStoreParameters.resource option.		SSLContextParameters
sslEnabledProtocols (security)	The list of protocols enabled for SSL connections. TLSv1.2, TLSv1.1 and TLSv1 are enabled by default.		String
sslEndpointAlgorithm (security)	The endpoint identification algorithm to validate server hostname using server certificate.	https	String
sslKeymanagerAlgorithm (security)	The algorithm used by key manager factory for SSL connections. Default value is the key manager factory algorithm configured for the Java Virtual Machine.	SunX509	String
sslKeyPassword (security)	The password of the private key in the key store file. This is optional for client.		String
sslKeystoreLocation (security)	The location of the key store file. This is optional for client and can be used for two-way authentication for client.		String
sslKeystorePassword (security)	The store password for the key store file. This is optional for client and only needed if ssl.keystore.location is configured.		String

Name	Description	Default	Type
sslKeystoreType (security)	The file format of the key store file. This is optional for client. Default value is JKS.	JKS	String
sslProtocol (security)	The SSL protocol used to generate the SSLContext. Default setting is TLS, which is fine for most cases. Allowed values in recent JVMs are TLS, TLSv1.1 and TLSv1.2. SSL, SSLv2 and SSLv3 may be supported in older JVMs, but their usage is discouraged due to known security vulnerabilities.		String
sslProvider (security)	The name of the security provider used for SSL connections. Default value is the default security provider of the JVM.		String
sslTrustmanagerAlgorithm (security)	The algorithm used by trust manager factory for SSL connections. Default value is the trust manager factory algorithm configured for the Java Virtual Machine.	PKIX	String
sslTruststoreLocation (security)	The location of the trust store file.		String
sslTruststorePassword (security)	The password for the trust store file.		String
sslTruststoreType (security)	The file format of the trust store file. Default value is JKS.	JKS	String

For more information about Producer/Consumer configuration see:

- <http://kafka.apache.org/documentation.html#newconsumerconfigs>
- <http://kafka.apache.org/documentation.html#producerconfigs>

66.6. MESSAGE HEADERS

The Kafka component supports 13 message header(s), which is/are listed below:

Name	Description	Default	Type
kafka.PARTITION_KEY (producer) Constant: PARTITION_KEY	Explicitly specify the partition.		Integer

Name	Description	Default	Type
kafka.PARTITION (consumer) Constant: PARTITION	The partition where the message was stored.		Integer
kafka.KEY (common) Constant: KEY	Required Producer: The key of the message in order to ensure that all related message goes in the same partition. Consumer: The key of the message if configured.		Object
kafka.TOPIC (consumer) Constant: TOPIC	The topic from where the message originated.		String
kafka.OVERRIDE_TOPIC (producer) Constant: OVERRIDE_TOPIC	The topic to which send the message (override and takes precedence), and the header is not preserved.		String
kafka.OFFSET (consumer) Constant: OFFSET	The offset of the message.		Long
kafka.HEADERS (consumer) Constant: HEADERS	The record headers.		Headers
kafka.LAST_RECORD_BEFORE_COMMIT (consumer) Constant: LAST_RECORD_BEFORE_COMMIT	Whether or not it's the last record before commit (only available if autoCommitEnable endpoint parameter is false).		Boolean
kafka.LAST_POLL_RECORD (consumer) Constant: LAST_POLL_RECORD	Indicates the last record within the current poll request (only available if autoCommitEnable endpoint parameter is false or allowManualCommit is true).		Boolean
kafka.TIMESTAMP (consumer) Constant: TIMESTAMP	The timestamp of the message.		Long

Name	Description	Default	Type
kafka.OVERRIDE_TIME_STAMP (producer) Constant: OVERRIDE_TIMESTAMP	The ProducerRecord also has an associated timestamp. If the user did provide a timestamp, the producer will stamp the record with the provided timestamp and the header is not preserved.		Long
kafka.RECORD_META (producer) Constant: KAFKA_RECORD_META	The metadata (only configured if recordMetadata endpoint parameter is true).		List
CamelKafkaManualCommit (consumer) Constant: MANUAL_COMMIT	Can be used for forcing manual offset commit when using Kafka consumer.		KafkaManualCommit

If you want to send a message to a dynamic topic then use `KafkaConstants.OVERRIDE_TOPIC` as it is used as a one-time header that is not sent along the message, and actually is removed in the producer.

66.7. USAGE

66.7.1. Consumer error handling

While kafka consumer is polling messages from the kafka broker, then errors can happen. This section describes what happens and what you can configure.

The consumer may throw exception when invoking the Kafka **poll** API. For example if the message cannot be de-serialized due invalid data, and many other kind of errors. Those errors are in the form of **KafkaException** which are either *retryable* or not. The exceptions which can be retried (**RetriableException**) will be retried again (with a poll timeout in between). All other kind of exceptions are handled according to the *pollOnError* configuration. This configuration has the following values:

- **DISCARD** will discard the message and continue to poll next message.
- **ERROR_HANDLER** will use Camel's error handler to process the exception, and afterwards continue to poll next message.
- **RECONNECT** will re-connect the consumer and try poll the message again.
- **RETRY** will let the consumer retry polling the same message again
- **STOP** will stop the consumer (have to be manually started/restarted if the consumer should be able to consume messages again).

The default is **ERROR_HANDLER** which will let Camel's error handler (if any configured) process the caused exception. And then afterwards continue to poll the next message. This behavior is similar to the *bridgeErrorHandler* option that Camel components have.

For advanced control then a custom implementation of **org.apache.camel.component.kafka.PollExceptionHandler** can be configured on the component level, which allows controlling which of the strategies to use for each exception.

66.7.2. Consumer error handling (advanced)

By default, Camel will poll using the **ERROR_HANDLER** to process exceptions. How Camel handles a message that results in an exception can be altered using the **breakOnFirstError** attribute in the configuration. Instead of continuing to poll the next message, Camel will instead commit the offset so that the message that caused the exception will be retried. This is similar to the **RETRY** polling strategy above.

```
KafkaComponent kafka = new KafkaComponent();
kafka.setBreakOnFirstError(true);
...
camelContext.addComponent("kafka", kafka);
```

It is recommended that you read the section below "Using manual commit with Kafka consumer" to understand how **breakOnFirstError** will work based on the **CommitManager** that is configured.

66.8. USING THE KAFKA IDEMPOTENT REPOSITORY

The **camel-kafka** library provides a Kafka topic-based idempotent repository.

This repository stores broadcasts all changes to idempotent state (add/remove) in a Kafka topic, and populates a local in-memory cache for each repository's process instance through event sourcing. The topic used must be unique per idempotent repository instance.

The mechanism does not have any requirements about the number of topic partitions; as the repository consumes from all partitions at the same time. It also does not have any requirements about the replication factor of the topic.

Each repository instance that uses the topic (e.g. typically on different machines running in parallel) controls its own consumer group, so in a cluster of 10 Camel processes using the same topic each will control its own offset.

On startup, the instance subscribes to the topic and rewinds the offset to the beginning, rebuilding the cache to the latest state. The cache will not be considered warmed up until one poll of **pollDurationMs** in length returns 0 records. Startup will not be completed until either the cache has warmed up, or 30 seconds go by; if the latter happens the idempotent repository may be in an inconsistent state until its consumer catches up to the end of the topic.

Be mindful of the format of the header used for the uniqueness check. By default, it uses Strings as the data types. When using primitive numeric formats, the header must be deserialized accordingly. Check the samples below for examples.

A **KafkaldempotentRepository** has the following properties:

Property	Description
topic	The name of the Kafka topic to use to broadcast changes. (required)
bootstrapServers	The bootstrap.servers property on the internal Kafka producer and consumer. Use this as shorthand if not setting consumerConfig and producerConfig . If used, this component will apply sensible default configurations for the producer and consumer.
producerConfig	Sets the properties that will be used by the Kafka producer that broadcasts changes. Overrides bootstrapServers , so must define the Kafka bootstrap.servers property itself
consumerConfig	Sets the properties that will be used by the Kafka consumer that populates the cache from the topic. Overrides bootstrapServers , so must define the Kafka bootstrap.servers property itself
maxCacheSize	How many of the most recently used keys should be stored in memory (default 1000).
pollDurationMs	The poll duration of the Kafka consumer. The local caches are updated immediately. This value will affect how far behind other peers that update their caches from the topic are relative to the idempotent consumer instance that sent the cache action message. The default value of this is 100 ms. If setting this value explicitly, be aware that there is a tradeoff between the remote cache liveness and the volume of network traffic between this repository's consumer and the Kafka brokers. The cache warmup process also depends on there being one poll that fetches nothing - this indicates that the stream has been consumed up to the current point. If the poll duration is excessively long for the rate at which messages are sent on the topic, there exists a possibility that the cache cannot be warmed up and will operate in an inconsistent state relative to its peers until it catches up.

The repository can be instantiated by defining the **topic** and **bootstrapServers**, or the **producerConfig** and **consumerConfig** property sets can be explicitly defined to enable features such as SSL/SASL. To use, this repository must be placed in the Camel registry, either manually or by registration as a bean in Spring/Blueprint, as it is **CamelContext** aware.

Sample usage is as follows:

```
KafkaldempotentRepository kafkaldempotentRepository = new
KafkaldempotentRepository("idempotent-db-inserts", "localhost:9091");

SimpleRegistry registry = new SimpleRegistry();
registry.put("insertDbIdemRepo", kafkaldempotentRepository); // must be registered in the registry, to
enable access to the CamelContext
CamelContext context = new CamelContext(registry);

// later in RouteBuilder...
from("direct:performInsert")
    .idempotentConsumer(header("id")).messageIdRepositoryRef("insertDbIdemRepo")
    // once-only insert into database
```

```
.end()
```

In XML:

```
<!-- simple -->
<bean id="insertDbIdemRepo"
  class="org.apache.camel.processor.idempotent.kafka.KafkaIdempotentRepository">
  <property name="topic" value="idempotent-db-inserts"/>
  <property name="bootstrapServers" value="localhost:9091"/>
</bean>

<!-- complex -->
<bean id="insertDbIdemRepo"
  class="org.apache.camel.processor.idempotent.kafka.KafkaIdempotentRepository">
  <property name="topic" value="idempotent-db-inserts"/>
  <property name="maxCacheSize" value="10000"/>
  <property name="consumerConfig">
    <props>
      <prop key="bootstrap.servers">localhost:9091</prop>
    </props>
  </property>
  <property name="producerConfig">
    <props>
      <prop key="bootstrap.servers">localhost:9091</prop>
    </props>
  </property>
</bean>
```

There are 3 alternatives to choose from when using idempotency with numeric identifiers. The first one is to use the static method **numericHeader** method from

org.apache.camel.component.kafka.serde.KafkaSerdeHelper to perform the conversion for you:

```
from("direct:performInsert")
  .idempotentConsumer(numericHeader("id")).messageIdRepositoryRef("insertDbIdemRepo")
  // once-only insert into database
  .end()
```

Alternatively, it is possible use a custom serializer configured via the route URL to perform the conversion:

```
public class CustomHeaderDeserializer extends DefaultKafkaHeaderDeserializer {
  private static final Logger LOG = LoggerFactory.getLogger(CustomHeaderDeserializer.class);

  @Override
  public Object deserialize(String key, byte[] value) {
    if (key.equals("id")) {
      BigInteger bi = new BigInteger(value);

      return String.valueOf(bi.longValue());
    } else {
      return super.deserialize(key, value);
    }
  }
}
```

Lastly, it is also possible to do so in a processor:

```
from(from).routeId("foo")
    .process(exchange -> {
        byte[] id = exchange.getIn().getHeader("id", byte[].class);

        BigInteger bi = new BigInteger(id);
        exchange.getIn().setHeader("id", String.valueOf(bi.longValue()));
    })
    .idempotentConsumer(header("id"))
    .messageIdRepositoryRef("kafkaIdempotentRepository")
    .to(to);
```

66.9. USING MANUAL COMMIT WITH KAFKA CONSUMER

By default the Kafka consumer will use auto commit, where the offset will be committed automatically in the background using a given interval.

In case you want to force manual commits, you can use **KafkaManualCommit** API from the Camel Exchange, stored on the message header. This requires to turn on manual commits by either setting the option **allowManualCommit** to **true** on the **KafkaComponent** or on the endpoint, for example:

```
KafkaComponent kafka = new KafkaComponent();
kafka.setAllowManualCommit(true);
...
camelContext.addComponent("kafka", kafka);
```

You can then use the **KafkaManualCommit** from Java code such as a Camel **Processor**:

```
public void process(Exchange exchange) {
    KafkaManualCommit manual =
        exchange.getIn().getHeader(KafkaConstants.MANUAL_COMMIT, KafkaManualCommit.class);
    manual.commit();
}
```

This will force a synchronous commit which will block until the commit is acknowledge on Kafka, or if it fails an exception is thrown. You can use an asynchronous commit as well by configuring the **KafkaManualCommitFactory** with the `DefaultKafkaManualAsyncCommitFactory` implementation.

The commit will then be done in the next consumer loop using the kafka asynchronous commit api. Be aware that records from a partition must be processed and committed by a unique thread. If not, this could lead with non consistent behaviors. This is mostly useful with aggregation's completion timeout strategies.

If you want to use a custom implementation of **KafkaManualCommit** then you can configure a custom **KafkaManualCommitFactory** on the **KafkaComponent** that creates instances of your custom implementation.

When configuring a consumer to use manual commit and a specific **CommitManager** it is important to understand how these influence the behavior of **breakOnFirstError**.

```
KafkaComponent kafka = new KafkaComponent();
kafka.setAutoCommitEnable(false);
kafka.setAllowManualCommit(true);
```

```
kafka.setBreakOnFirstError(true);
kafka.setKafkaManualCommitFactory(new DefaultKafkaManualCommitFactory());
...
camelContext.addComponent("kafka", kafka);
```

When the **CommitManager** is left to the default **NoopCommitManager** then **breakOnFirstError** will not automatically commit the offset so that the message with an error is retried. The consumer must manage that in the route using **KafkaManualCommit**.

When the **CommitManager** is changed to either the synchronous or asynchronous manager then **breakOnFirstError** will automatically commit the offset so that the message with an error is retried. This message will be continually retried until it can be processed without an error.

NOTE

- Records from a partition must be processed and committed by the same thread as the consumer. This means that certain EIPs, async or concurrent operations in the DSL may cause the commit to fail. In such circumstances, trying to commit the transaction will cause the Kafka client to throw a **java.util.ConcurrentModificationException** exception with the message **KafkaConsumer is not safe for multi-threaded access**. To prevent this from happening, redesign your route to avoid those operations.
- This is mostly useful with aggregation's completion timeout strategies.

66.10. PAUSABLE CONSUMERS

The Kafka component supports pausable consumers. This type of consumer can pause consuming data based on conditions external to the component itself, such as an external system being unavailable or other transient conditions.

```
from("kafka:topic")
    .pausable(new KafkaConsumerListener(), () -> canContinue()) // the pausable check gets called if
the exchange fails to be processed ...
    .routeId("pausable-route")
    .process(this::process) // Kafka consumer will be paused if this one throws an exception ...
    .to("some:destination"); // or this one
```

In this example, consuming messages can pause (by calling the Kafka's Consumer pause method) if the result from **canContinue** is false.

IMPORTANT

The pausable EIP is meant to be used as a support mechanism when **there is an exception** somewhere in the route that prevents the exchange from being processed. More specifically, the check called by the **pausable** EIP should be used to test for transient conditions preventing the exchange from being processed.

NOTE

Most users should prefer using the `routeId`, which offers better control of the route.

66.11. KAFKA HEADERS PROPAGATION

When consuming messages from Kafka, headers will be propagated to camel exchange headers automatically. Producing flow backed by same behaviour – camel headers of particular exchange will be propagated to kafka message headers.

Since kafka headers allows only **byte[]** values, in order camel exchange header to be propagated its value should be serialized to **bytes[]**, otherwise header will be skipped. Following header value types are supported: **String**, **Integer**, **Long**, **Double**, **Boolean**, **byte[]**. Note: all headers propagated **from** kafka **to** camel exchange will contain **byte[]** value by default. In order to override default functionality uri parameters can be set: **headerDeserializer** for **from** route and **headerSerializer** for **to** route. Example:

```
from("kafka:my_topic?headerDeserializer=#myDeserializer")
...
.to("kafka:my_topic?headerSerializer=#mySerializer")
```

By default all headers are being filtered by **KafkaHeaderFilterStrategy**. Strategy filters out headers which start with **Camel** or **org.apache.camel** prefixes. Default strategy can be overridden by using **headerFilterStrategy** uri parameter in both **to** and **from** routes:

```
from("kafka:my_topic?headerFilterStrategy=#myStrategy")
...
.to("kafka:my_topic?headerFilterStrategy=#myStrategy")
```

myStrategy object should be subclass of **HeaderFilterStrategy** and must be placed in the Camel registry, either manually or by registration as a bean in Spring/Blueprint, as it is **CamelContext** aware.

66.12. KAFKA TRANSACTION

You need to add **transactional.id**, **enable.idempotence** and **retries** in **additional-properties** to enable kafka transaction with the producer.

```
from("direct:transaction")
.to("kafka:my_topic?additional-properties[transactional.id]=1234&additional-
properties[enable.idempotence]=true&additional-properties[retries]=5");
```

At the end of exchange routing, the kafka producer would commit the transaction or abort it if there is an Exception throwing or the exchange is **RollbackOnly**. Since Kafka does not support transactions in multi threads, it will throw **ProducerFencedException** if there is another producer with the same **transaction.id** to make the transactional request.

It would work with JTA **camel-jta** by using **transacted()** and if it involves some resources (SQL or JMS), which supports XA, then they would work in tandem, where they both will either commit or rollback at the end of the exchange routing. In some cases, if the JTA transaction manager fails to commit (during the 2PC processing), but kafka transaction has been committed before and there is no chance to roll back the changes since the kafka transaction does not support JTA/XA spec. There is still a risk with the data consistency.

66.13. SETTING KERBEROS CONFIG FILE

Configure the 'krb5.conf' file directly through the API:

```
static {
    KafkaComponent.setKerberosConfigLocation("path/to/config/file");
}
```

66.14. BATCHING CONSUMER

To use a Kafka batching consumer with Camel, an application has to set the configuration **batching** to **true**.

The received records are stored in a list in the exchange used in the pipeline. As such, it is possible to commit individually every record or the whole batch at once by committing the last exchange on the list.

The size of the batch is controlled by the option **maxPollRecords**.

To avoid blocking for too long, waiting for the whole set of records to fill the batch, it is possible to use the **pollTimeoutMs** option to set a timeout for the polling. In this case, the batch may contain less messages than set in the **maxPollRecords**.

66.14.1. Automatic Commits

By default, Camel uses automatic commits when using batch processing. In this case, Camel automatically commits the records after they have been successfully processed by the application.

In case of failures, the records will not be processed. The code below provides an example of this approach:

```
public void configure() {
    from("kafka:topic?
groupId=myGroup&pollTimeoutMs=1000&batching=true&maxPollRecords=10&autoOffsetReset=earlies
").process(e -> {
    // The received records are stored as exchanges in a list. This gets the list of those exchanges
    final List<?> exchanges = e.getMessage().getBody(List.class);

    // Ensure we are actually receiving what we are asking for
    if (exchanges == null || exchanges.isEmpty()) {
        return;
    }

    // The records from the batch are stored in a list of exchanges in the original exchange. To
    process, we iterate over that list
    for (Object obj : exchanges) {
        if (obj instanceof Exchange exchange) {
            LOG.info("Processing exchange with body {}",
exchange.getMessage().getBody(String.class));
        }
    }
    }).to(KafkaTestUtil.MOCK_RESULT);
}
```

66.14.1.1. Handling Errors with Automatic Commits

When using automatic commits, Camel will not commit records if there is a failure in processing. Because of this, there is a risk that records could be reprocessed multiple times.

It is recommended to implement appropriate error handling mechanisms and patterns (i.e.; such as dead-letter queues), to prevent failed records from blocking processing progress.

The code below provides an example of handling errors with automatic commits:

```
public void configure() {
    /*
     * We want to use continued here, so that Camel auto-commits the batch even though part of it has
     * failed. In a
     * production scenario, applications should probably send these records to a separate topic or fix the
     * condition
     * that lead to the failure
     */
    onException(IllegalArgumentException.class).process(exchange -> {
        LOG.warn("Failed to process batch {}", exchange.getMessage().getBody());
        LOG.warn("Failed to process due to {}",
exchange.getProperty(Exchange.EXCEPTION_CAUGHT, Throwable.class).getMessage());
    }).continued(true);

    from("kafka:topic?
groupId=myGroup&pollTimeoutMs=1000&batching=true&maxPollRecords=10&autoOffsetReset=earlies
").process(e -> {
    // The received records are stored as exchanges in a list. This gets the list of those exchanges
    final List<?> exchanges = e.getMessage().getBody(List.class);

    // Ensure we are actually receiving what we are asking for
    if (exchanges == null || exchanges.isEmpty()) {
        return;
    }

    // The records from the batch are stored in a list of exchanges in the original exchange.
    int i = 0;
    for (Object o : exchanges) {
        if (o instanceof Exchange exchange) {
            i++;
            LOG.info("Processing exchange with body {}",
exchange.getMessage().getBody(String.class));

            if (i == 4) {
                throw new IllegalArgumentException("Failed to process record");
            }
        }
    }
    }).to(KafkaTestUtil.MOCK_RESULT);
}
```

66.14.2. Manual Commits

When working with batch processing with manual commits, it's up to the application to commit the records, and handle the outcome of potentially invalid records.

The code below provides an example of this approach:

```
public void configure() {
    from("kafka:topic?
batching=true&allowManualCommit=true&maxPollRecords=100&kafkaManualCommitFactory=#class:or
g.apache.camel.component.kafka.consumer.DefaultKafkaManualCommitFactory")
    .process(e -> {
```

```

// The received records are stored as exchanges in a list. This gets the list of those exchanges
final List<?> exchanges = e.getMessage().getBody(List.class);

// Ensure we are actually receiving what we are asking for
if (exchanges == null || exchanges.isEmpty()) {
    return;
}

/*
Every exchange in that list should contain a reference to the manual commit object. We use the
reference
for the last exchange in the list to commit the whole batch
*/
final Object tmp = exchanges.getLast();
if (tmp instanceof Exchange exchange) {
    KafkaManualCommit manual =
        exchange.getMessage().getHeader(KafkaConstants.MANUAL_COMMIT,
KafkaManualCommit.class);
    LOG.debug("Performing manual commit");
    manual.commit();
    LOG.debug("Done performing manual commit");
}
});
}

```

66.14.3. Dealing with long polling timeouts

In some cases, applications may want the polling process to have a long timeout (see: **pollTimeoutMs**).

To properly do so, first make sure to have a max polling interval that is higher than the polling timeout (see: **maxPollIntervalMs**).

Then, increase the shutdown timeout to ensure that committing, closing and other Kafka operations are not abruptly aborted. For instance:

```

public void configure() {
    // Note that this can be configured in other ways
    getCamelContext().getShutdownStrategy().setTimeout(10000);

    // route setup ...
}

```

66.15. CUSTOM SUBSCRIPTION ADAPTERS

Applications with complex subscription logic may provide a custom bean to handle the subscription process. To so, it is necessary to implement the interface **SubscribeAdapter**.

Example subscriber adapter that subscribes to a set of Kafka topics or patterns

```

public class CustomSubscribeAdapter implements SubscribeAdapter {
    @Override
    public void subscribe(Consumer<?, ?> consumer, ConsumerRebalanceListener reBalanceListener,
TopicInfo topicInfo) {
        if (topicInfo.isPattern()) {

```

```

        consumer.subscribe(topicInfo.getPattern(), reBalanceListener);
    } else {
        consumer.subscribe(topicInfo.getTopics(), reBalanceListener);
    }
}
}

```

Then, it is necessary to add it as named bean instance to the registry:

Add to registry example

```

context.getRegistry().bind(KafkaConstants.KAFKA_SUBSCRIBE_ADAPTER, new
CustomSubscribeAdapter());

```

66.16. INTEROPERABILITY

66.16.1. JMS

When interoperating Kafka and JMS, it may be necessary to coerce the JMS headers into their expected type.

For instance, when consuming messages from Kafka carrying JMS headers and then sending them to a JMS broker, those headers are first deserialized into a byte array. Then, the **camel-jms** component tries to coerce this byte array into the specific type used by. However, both the origin endpoint as well as how this was setup on the code itself may affect how the data is serialized and deserialized. As such, it is not feasible to naively assume the data type of the byte array.

To address this issue, we provide a custom header deserializer to force Kafka to de-serialize the JMS data according to the JMS specification. This approach ensures that the headers are properly interpreted and processed by the camel-jms component.

Due to the inherent complexity of each possible system and endpoint, it may not be possible for this deserializer to cover all possible scenarios. As such, it is provided as model that can be modified and/or adapted for the specific needs of each application.

To utilize this solution, you need to modify the route URI on the consumer end of the pipeline by including the **headerDeserializer** option. For example:

```

from("kafka:topic?
headerDeserializer=#class:org.apache.camel.component.kafka.consumer.support.interop.JMSDeserializer")
.to("...");

```

66.17. EXAMPLES

66.17.1. Consuming messages from Kafka

Here is the minimal route you need in order to read messages from Kafka.

```

from("kafka:test?brokers=localhost:9092")
.log("Message received from Kafka : ${body}")
.log("  on the topic ${headers[kafka.TOPIC]}")
.log("  on the partition ${headers[kafka.PARTITION]}")

```

```
.log("    with the offset ${headers[kafka.OFFSET]}")
.log("    with the key ${headers[kafka.KEY]}")
```

If you need to consume messages from multiple topics you can use a comma separated list of topic names.

```
from("kafka:test,test1,test2?brokers=localhost:9092")
.log("Message received from Kafka : ${body}")
.log("    on the topic ${headers[kafka.TOPIC]}")
.log("    on the partition ${headers[kafka.PARTITION]}")
.log("    with the offset ${headers[kafka.OFFSET]}")
.log("    with the key ${headers[kafka.KEY]}")
```

It's also possible to subscribe to multiple topics giving a pattern as the topic name and using the **topicsPattern** option.

```
from("kafka:test*?brokers=localhost:9092&topicsPattern=true")
.log("Message received from Kafka : ${body}")
.log("    on the topic ${headers[kafka.TOPIC]}")
.log("    on the partition ${headers[kafka.PARTITION]}")
.log("    with the offset ${headers[kafka.OFFSET]}")
.log("    with the key ${headers[kafka.KEY]}")
```

When consuming messages from Kafka you can use your own offset management and not delegate this management to Kafka. In order to keep the offsets the component needs a **StateRepository** implementation such as **FileStateRepository**. This bean should be available in the registry. Here how to use it :

```
// Create the repository in which the Kafka offsets will be persisted
FileStateRepository repository = FileStateRepository.fileStateRepository(new
File("/path/to/repo.dat"));

// Bind this repository into the Camel registry
Registry registry = createCamelRegistry();
registry.bind("offsetRepo", repository);

// Configure the camel context
DefaultCamelContext camelContext = new DefaultCamelContext(registry);
camelContext.addRoutes(new RouteBuilder() {
    @Override
    public void configure() throws Exception {
        from("kafka:" + TOPIC + "?brokers=localhost:{{kafkaPort}}" +
            // Setup the topic and broker address
            "&groupId=A" +
            // The consumer processor group ID
            "&autoOffsetReset=earliest" +
            // Ask to start from the beginning if we have unknown offset
            "&offsetRepository=#offsetRepo")
            // Keep the offsets in the previously configured repository
            .to("mock:result");
    }
});
```

66.17.2. Producing messages to Kafka

Here is the minimal route you need in order to write messages to Kafka.

```
from("direct:start")
    .setBody(constant("Message from Camel")) // Message to send
    .setHeader(KafkaConstants.KEY, constant("Camel")) // Key of the message
    .to("kafka:test?brokers=localhost:9092");
```

66.17.3. SSL configuration

You have 2 different ways to configure the SSL communication on the Kafka` component.

The first way is through the many SSL endpoint parameters

```
from("kafka:" + TOPIC + "?brokers=localhost:{{kafkaPort}}" +
    "&groupId=A" +
    "&sslKeystoreLocation=/path/to/keystore.jks" +
    "&sslKeystorePassword=changeit" +
    "&sslKeyPassword=changeit" +
    "&securityProtocol=SSL")
    .to("mock:result");
```

The second way is to use the **sslContextParameters** endpoint parameter.

```
// Configure the SSLContextParameters object
KeyStoreParameters ksp = new KeyStoreParameters();
ksp.setResource("/path/to/keystore.jks");
ksp.setPassword("changeit");
KeyManagersParameters kmp = new KeyManagersParameters();
kmp.setKeyStore(ksp);
kmp.setKeyPassword("changeit");
SSLContextParameters scp = new SSLContextParameters();
scp.setKeyManagers(kmp);

// Bind this SSLContextParameters into the Camel registry
Registry registry = createCamelRegistry();
registry.bind("ssl", scp);

// Configure the camel context
DefaultCamelContext camelContext = new DefaultCamelContext(registry);
camelContext.addRoutes(new RouteBuilder() {
    @Override
    public void configure() throws Exception {
        from("kafka:" + TOPIC + "?brokers=localhost:{{kafkaPort}}" +
            // Setup the topic and broker address
            "&groupId=A" +
            // The consumer processor group ID
            "&sslContextParameters=#ssl" +
            // The security protocol
            "&securityProtocol=SSL")
            // Reference the SSL configuration
            .to("mock:result");
    }
});
```

66.18. SPRING BOOT AUTO-CONFIGURATION

The component supports 117 options, which are listed below.

Name	Description	Default	Type
camel.component.kafka.additional-properties	Sets additional properties for either kafka consumer or kafka producer in case they can't be set directly on the camel configurations (e.g: new Kafka properties that are not reflected yet in Camel configurations), the properties have to be prefixed with <code>additionalProperties..</code> E.g: <code>additionalProperties.transactional.id=12345&additionalProperties.schema.registry.url=http://localhost:8811/avro.</code>		Map
camel.component.kafka.allow-manual-commit	Whether to allow doing manual commits via <code>KafkaManualCommit</code> . If this option is enabled then an instance of <code>KafkaManualCommit</code> is stored on the Exchange message header, which allows end users to access this API and perform manual offset commits via the Kafka consumer.	false	Boolean
camel.component.kafka.auto-commit-enable	If true, periodically commit to ZooKeeper the offset of messages already fetched by the consumer. This committed offset will be used when the process fails as the position from which the new consumer will begin.	true	Boolean
camel.component.kafka.auto-commit-interval-ms	The frequency in ms that the consumer offsets are committed to zookeeper.	5000	Integer
camel.component.kafka.auto-commit-on-stop	Whether to perform an explicit auto commit when the consumer stops to ensure the broker has a commit from the last consumed message. This requires the option <code>autoCommitEnable</code> is turned on. The possible values are: <code>sync</code> , <code>async</code> , or <code>none</code> . And <code>sync</code> is the default value.	sync	String
camel.component.kafka.auto-offset-reset	What to do when there is no initial offset in ZooKeeper or if an offset is out of range: <code>earliest</code> : automatically reset the offset to the earliest offset <code>latest</code> : automatically reset the offset to the latest offset <code>fail</code> : throw exception to the consumer.	latest	String

Name	Description	Default	Type
camel.component.kafka.autowired-enabled	Whether autowiring is enabled. This is used for automatic autowiring options (the option must be marked as autowired) by looking up in the registry to find if there is a single instance of matching type, which then gets configured on the component. This can be used for automatic configuring JDBC data sources, JMS connection factories, AWS Clients, etc.	true	Boolean
camel.component.kafka.batch-with-individual-headers	If this feature is enabled and a single element of a batch is an Exchange or Message, the producer will generate individual kafka header values for it by using the batch Message to determine the values. Normal behavior consists of always using the same header values (which are determined by the parent Exchange which contains the Iterable or Iterator).	false	Boolean
camel.component.kafka.batching	Whether to use batching for processing or streaming. The default is false, which uses streaming.	false	Boolean
camel.component.kafka.break-on-first-error	This options controls what happens when a consumer is processing an exchange and it fails. If the option is false then the consumer continues to the next message and processes it. If the option is true then the consumer breaks out, and will seek back to offset of the message that caused a failure, and then re-attempt to process this message. However this can lead to endless processing of the same message if its bound to fail every time, eg a poison message. Therefore its recommended to deal with that for example by using Camel's error handler.	false	Boolean
camel.component.kafka.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
camel.component.kafka.brokers	URL of the Kafka brokers to use. The format is host1:port1,host2:port2, and the list can be a subset of brokers or a VIP pointing to a subset of brokers. This option is known as bootstrap.servers in the Kafka documentation.		String

Name	Description	Default	Type
camel.component.kafka.buffer-memory-size	The total bytes of memory the producer can use to buffer records waiting to be sent to the server. If records are sent faster than they can be delivered to the server the producer will either block or throw an exception based on the preference specified by <code>block.on.buffer.full</code> . This setting should correspond roughly to the total memory the producer will use, but is not a hard bound since not all memory the producer uses is used for buffering. Some additional memory will be used for compression (if compression is enabled) as well as for maintaining in-flight requests.	33554432	Integer
camel.component.kafka.check-crcs	Automatically check the CRC32 of the records consumed. This ensures no on-the-wire or on-disk corruption to the messages occurred. This check adds some overhead, so it may be disabled in cases seeking extreme performance.	true	Boolean
camel.component.kafka.client-id	The client id is a user-specified string sent in each request to help trace calls. It should logically identify the application making the request.		String
camel.component.kafka.commit-timeout-ms	The maximum time, in milliseconds, that the code will wait for a synchronous commit to complete. The option is a <code>java.lang.Long</code> type.	5000	Long
camel.component.kafka.compression-codec	This parameter allows you to specify the compression codec for all data generated by this producer. Valid values are <code>none</code> , <code>gzip</code> and <code>snappy</code> .	none	String
camel.component.kafka.configuration	Allows to pre-configure the Kafka component with common options that the endpoints will reuse. The option is a <code>org.apache.camel.component.kafka.KafkaConfiguration</code> type.		KafkaConfiguration
camel.component.kafka.connection-max-idle-ms	Close idle connections after the number of milliseconds specified by this config.	540000	Integer
camel.component.kafka.consumer-request-timeout-ms	The configuration controls the maximum amount of time the client will wait for the response of a request. If the response is not received before the timeout elapses the client will resend the request if necessary or fail the request if retries are exhausted.	40000	Integer

Name	Description	Default	Type
camel.component. .kafka.consumers- count	The number of consumers that connect to kafka server. Each consumer is run on a separate thread, that retrieves and process the incoming data.	1	Integer
camel.component. .kafka.create- consumer- backoff-interval	The delay in millis seconds to wait before trying again to create the kafka consumer (kafka-client).	5000	Long
camel.component. .kafka.create- consumer- backoff-max- attempts	Maximum attempts to create the kafka consumer (kafka-client), before eventually giving up and failing. Error during creating the consumer may be fatal due to invalid configuration and as such recovery is not possible. However, one part of the validation is DNS resolution of the bootstrap broker hostnames. This may be a temporary networking problem, and could potentially be recoverable. While other errors are fatal, such as some invalid kafka configurations. Unfortunately, kafka-client does not separate this kind of errors. Camel will by default retry forever, and therefore never give up. If you want to give up after many attempts then set this option and Camel will then when giving up terminate the consumer. To try again, you can manually restart the consumer by stopping, and starting the route.		Integer
camel.component. .kafka.delivery- timeout-ms	An upper bound on the time to report success or failure after a call to send() returns. This limits the total time that a record will be delayed prior to sending, the time to await acknowledgement from the broker (if expected), and the time allowed for retrievable send failures.	12000 0	Integer
camel.component. .kafka.enable- idempotence	If set to 'true' the producer will ensure that exactly one copy of each message is written in the stream. If 'false', producer retries may write duplicates of the retried message in the stream. If set to true this option will require max.in.flight.requests.per.connection to be set to 1 and retries cannot be zero and additionally acks must be set to 'all'.	false	Boolean
camel.component. .kafka.enabled	Whether to enable auto configuration of the kafka component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.kafka.fetch-max-bytes	The maximum amount of data the server should return for a fetch request This is not an absolute maximum, if the first message in the first non-empty partition of the fetch is larger than this value, the message will still be returned to ensure that the consumer can make progress. The maximum message size accepted by the broker is defined via <code>message.max.bytes</code> (broker config) or <code>max.message.bytes</code> (topic config). Note that the consumer performs multiple fetches in parallel.	52428800	Integer
camel.component.kafka.fetch-min-bytes	The minimum amount of data the server should return for a fetch request. If insufficient data is available the request will wait for that much data to accumulate before answering the request.	1	Integer
camel.component.kafka.fetch-wait-max-ms	The maximum amount of time the server will block before answering the fetch request if there isn't sufficient data to immediately satisfy <code>fetch.min.bytes</code> .	500	Integer
camel.component.kafka.group-id	A string that uniquely identifies the group of consumer processes to which this consumer belongs. By setting the same group id multiple processes indicate that they are all part of the same consumer group. This option is required for consumers.		String
camel.component.kafka.group-instance-id	A unique identifier of the consumer instance provided by the end user. Only non-empty strings are permitted. If set, the consumer is treated as a static member, which means that only one instance with this ID is allowed in the consumer group at any time. This can be used in combination with a larger session timeout to avoid group rebalances caused by transient unavailability (e.g. process restarts). If not set, the consumer will join the group as a dynamic member, which is the traditional behavior.		String
camel.component.kafka.header-deserializer	To use a custom <code>KafkaHeaderDeserializer</code> to deserialize kafka headers values. The option is a <code>org.apache.camel.component.kafka.serde.KafkaHeaderDeserializer</code> type.		<code>KafkaHeaderDeserializer</code>
camel.component.kafka.header-filter-strategy	To use a custom <code>HeaderFilterStrategy</code> to filter header to and from Camel message. The option is a <code>org.apache.camel.spi.HeaderFilterStrategy</code> type.		<code>HeaderFilterStrategy</code>

Name	Description	Default	Type
camel.component.kafka.header-serializer	To use a custom KafkaHeaderSerializer to serialize kafka headers values. The option is a <code>org.apache.camel.component.kafka.serde.KafkaHeaderSerializer</code> type.		KafkaHeaderSerializer
camel.component.kafka.health-check-consumer-enabled	Used for enabling or disabling all consumer based health checks from this component.	true	Boolean
camel.component.kafka.health-check-producer-enabled	Used for enabling or disabling all producer based health checks from this component. Notice: Camel has by default disabled all producer based health-checks. You can turn on producer checks globally by setting <code>camel.health.producersEnabled=true</code> .	true	Boolean
camel.component.kafka.heartbeat-interval-ms	The expected time between heartbeats to the consumer coordinator when using Kafka's group management facilities. Heartbeats are used to ensure that the consumer's session stays active and to facilitate rebalancing when new consumers join or leave the group. The value must be set lower than <code>session.timeout.ms</code> , but typically should be set no higher than 1/3 of that value. It can be adjusted even lower to control the expected time for normal rebalances.	3000	Integer
camel.component.kafka.interceptor-classes	Sets interceptors for producer or consumers. Producer interceptors have to be classes implementing <code>org.apache.kafka.clients.producer.ProducerInterceptor</code> or Consumer interceptors have to be classes implementing <code>org.apache.kafka.clients.consumer.ConsumerInterceptor</code> Note that if you use Producer interceptor on a consumer it will throw a class cast exception in runtime.		String

Name	Description	Default	Type
camel.component.kafka.isolation-level	Controls how to read messages written transactionally. If set to <code>read_committed</code> , <code>consumer.poll()</code> will only return transactional messages which have been committed. If set to <code>read_uncommitted</code> (the default), <code>consumer.poll()</code> will return all messages, even transactional messages which have been aborted. Non-transactional messages will be returned unconditionally in either mode. Messages will always be returned in offset order. Hence, in <code>read_committed</code> mode, <code>consumer.poll()</code> will only return messages up to the last stable offset (LSO), which is the one less than the offset of the first open transaction. In particular, any messages appearing after messages belonging to ongoing transactions will be withheld until the relevant transaction has been completed. As a result, <code>read_committed</code> consumers will not be able to read up to the high watermark when there are in flight transactions. Further, when in <code>read_committed</code> the <code>seekToEnd</code> method will return the LSO.	<code>read_uncommitted</code>	String
camel.component.kafka.kafka-client-factory	Factory to use for creating <code>org.apache.kafka.clients.consumer.KafkaConsumer</code> and <code>org.apache.kafka.clients.producer.KafkaProducer</code> instances. This allows to configure a custom factory to create instances with logic that extends the vanilla Kafka clients. The option is a <code>org.apache.camel.component.kafka.KafkaClientFactory</code> type.		<code>KafkaClientFactory</code>
camel.component.kafka.kafka-manual-commit-factory	Factory to use for creating <code>KafkaManualCommit</code> instances. This allows to plugin a custom factory to create custom <code>KafkaManualCommit</code> instances in case special logic is needed when doing manual commits that deviates from the default implementation that comes out of the box. The option is a <code>org.apache.camel.component.kafka.KafkaManualCommitFactory</code> type.		<code>KafkaManualCommitFactory</code>
camel.component.kafka.kerberos-before-relogin-min-time	Login thread sleep time between refresh attempts.	60000	Integer
camel.component.kafka.kerberos-config-location	Location of the kerberos config file.		String

Name	Description	Default	Type
camel.component.kafka.kerberos-init-cmd	Kerberos kinit command path. Default is /usr/bin/kinit.	/usr/bin/kinit	String
camel.component.kafka.kerberos-principal-to-local-rules	A list of rules for mapping from principal names to short names (typically operating system usernames). The rules are evaluated in order and the first rule that matches a principal name is used to map it to a short name. Any later rules in the list are ignored. By default, principal names of the form {username}/{hostname}{REALM} are mapped to {username}. For more details on the format please see the security authorization and acls documentation.. Multiple values can be separated by comma.	DEFAULT	String
camel.component.kafka.kerberos-renew-jitter	Percentage of random jitter added to the renewal time.		Double
camel.component.kafka.kerberos-renew-window-factor	Login thread will sleep until the specified window factor of time from last refresh to ticket's expiry has been reached, at which time it will try to renew the ticket.		Double
camel.component.kafka.key	The record key (or null if no key is specified). If this option has been configured then it take precedence over header KafkaConstants#KEY.		String
camel.component.kafka.key-deserializer	Deserializer class for key that implements the Deserializer interface.	org.apache.kafka.common.serialization.StringDeserializer	String
camel.component.kafka.key-serializer	The serializer class for keys (defaults to the same as for messages if nothing is given).	org.apache.kafka.common.serialization.StringSerializer	String

Name	Description	Default	Type
camel.component.kafka.lazy-start-producer	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
camel.component.kafka.linger-ms	The producer groups together any records that arrive in between request transmissions into a single batched request. Normally this occurs only under load when records arrive faster than they can be sent out. However in some circumstances the client may want to reduce the number of requests even under moderate load. This setting accomplishes this by adding a small amount of artificial delay that is, rather than immediately sending out a record the producer will wait for up to the given delay to allow other records to be sent so that the sends can be batched together. This can be thought of as analogous to Nagle's algorithm in TCP. This setting gives the upper bound on the delay for batching: once we get batch.size worth of records for a partition it will be sent immediately regardless of this setting, however if we have fewer than this many bytes accumulated for this partition we will 'linger' for the specified time waiting for more records to show up. This setting defaults to 0 (i.e. no delay). Setting linger.ms=5, for example, would have the effect of reducing the number of requests sent but would add up to 5ms of latency to records sent in the absense of load.	0	Integer
camel.component.kafka.max-block-ms	The configuration controls how long sending to kafka will block. These methods can be blocked for multiple reasons. For e.g: buffer full, metadata unavailable. This configuration imposes maximum limit on the total time spent in fetching metadata, serialization of key and value, partitioning and allocation of buffer memory when doing a send(). In case of partitionsFor(), this configuration imposes a maximum time threshold on waiting for metadata.	60000	Integer

Name	Description	Default	Type
camel.component.kafka.max-in-flight-request	The maximum number of unacknowledged requests the client will send on a single connection before blocking. Note that if this setting is set to be greater than 1 and there are failed sends, there is a risk of message re-ordering due to retries (i.e., if retries are enabled).	5	Integer
camel.component.kafka.max-partition-fetch-bytes	The maximum amount of data per-partition the server will return. The maximum total memory used for a request will be <code>#partitions max.partition.fetch.bytes</code> . This size must be at least as large as the maximum message size the server allows or else it is possible for the producer to send messages larger than the consumer can fetch. If that happens, the consumer can get stuck trying to fetch a large message on a certain partition.	1048576	Integer
camel.component.kafka.max-poll-interval-ms	The maximum delay between invocations of <code>poll()</code> when using consumer group management. This places an upper bound on the amount of time that the consumer can be idle before fetching more records. If <code>poll()</code> is not called before expiration of this timeout, then the consumer is considered failed and the group will rebalance in order to reassign the partitions to another member. The option is a <code>java.lang.Long</code> type.		Long
camel.component.kafka.max-poll-records	The maximum number of records returned in a single call to <code>poll()</code> .	500	Integer
camel.component.kafka.max-request-size	The maximum size of a request. This is also effectively a cap on the maximum record size. Note that the server has its own cap on record size which may be different from this. This setting will limit the number of record batches the producer will send in a single request to avoid sending huge requests.	1048576	Integer
camel.component.kafka.metadata-max-age-ms	The period of time in milliseconds after which we force a refresh of metadata even if we haven't seen any partition leadership changes to proactively discover any new brokers or partitions.	300000	Integer
camel.component.kafka.metric-reporters	A list of classes to use as metrics reporters. Implementing the <code>MetricReporter</code> interface allows plugging in classes that will be notified of new metric creation. The <code>JmxReporter</code> is always included to register JMX statistics.		String

Name	Description	Default	Type
camel.component.kafka.metrics-sample-window-ms	The number of samples maintained to compute metrics.	30000	Integer
camel.component.kafka.no-of-metrics-sample	The number of samples maintained to compute metrics.	2	Integer
camel.component.kafka.offset-repository	The offset repository to use in order to locally store the offset of each partition of the topic. Defining one will disable the autocommit. The option is a <code>org.apache.camel.spi.StateRepository<java.lang.String, java.lang.String></code> type.		StateRepository
camel.component.kafka.partition-assignor	The class name of the partition assignment strategy that the client will use to distribute partition ownership amongst consumer instances when group management is used.	<code>org.apache.kafka.clients.consumer.RangeAssignor</code>	String
camel.component.kafka.partition-key	The partition to which the record will be sent (or null if no partition was specified). If this option has been configured then it take precedence over header <code>KafkaConstants#PARTITION_KEY</code> .		Integer
camel.component.kafka.partitionner	The partitioner class for partitioning messages amongst sub-topics. The default partitioner is based on the hash of the key.	<code>org.apache.kafka.clients.producer.internals.DefaultPartitioner</code>	String
camel.component.kafka.partitionner-ignore-keys	Whether the message keys should be ignored when computing the partition. This setting has effect only when partitioner is not set.	false	Boolean
camel.component.kafka.poll-exception-strategy	To use a custom strategy with the consumer to control how to handle exceptions thrown from the Kafka broker while pooling messages. The option is a <code>org.apache.camel.component.kafka.PollExceptionHandler</code> type.		PollExceptionHandler

Name	Description	Default	Type
camel.component.kafka.poll-on-error	What to do if kafka threw an exception while polling for new messages. Will by default use the value from the component configuration unless an explicit value has been configured on the endpoint level. DISCARD will discard the message and continue to poll next message. ERROR_HANDLER will use Camel's error handler to process the exception, and afterwards continue to poll next message. RECONNECT will re-connect the consumer and try poll the message again. RETRY will let the consumer retry polling the same message again. STOP will stop the consumer (have to be manually started/restarted if the consumer should be able to consume messages again).		PollOnError
camel.component.kafka.poll-timeout-ms	The timeout used when polling the KafkaConsumer. The option is a java.lang.Long type.	5000	Long
camel.component.kafka.pre-validate-host-and-port	Whether to eager validate that broker host:port is valid and can be DNS resolved to known host during starting this consumer. If the validation fails, then an exception is thrown, which makes Camel fail fast. Disabling this will postpone the validation after the consumer is started, and Camel will keep re-connecting in case of validation or DNS resolution error.	true	Boolean
camel.component.kafka.producer-batch-size	The producer will attempt to batch records together into fewer requests whenever multiple records are being sent to the same partition. This helps performance on both the client and the server. This configuration controls the default batch size in bytes. No attempt will be made to batch records larger than this size. Requests sent to brokers will contain multiple batches, one for each partition with data available to be sent. A small batch size will make batching less common and may reduce throughput (a batch size of zero will disable batching entirely). A very large batch size may use memory a bit more wastefully as we will always allocate a buffer of the specified batch size in anticipation of additional records.	16384	Integer
camel.component.kafka.queue-buffering-max-messages	The maximum number of unsent messages that can be queued up the producer when using async mode before either the producer must be blocked or data must be dropped.	10000	Integer

Name	Description	Default	Type
camel.component. .kafka.receive- buffer-bytes	The size of the TCP receive buffer (SO_RCVBUF) to use when reading data.	65536	Integer
camel.component. .kafka.reconnect- backoff-max-ms	The maximum amount of time in milliseconds to wait when reconnecting to a broker that has repeatedly failed to connect. If provided, the backoff per host will increase exponentially for each consecutive connection failure, up to this maximum. After calculating the backoff increase, 20% random jitter is added to avoid connection storms.	1000	Integer
camel.component. .kafka.reconnect- backoff-ms	The amount of time to wait before attempting to reconnect to a given host. This avoids repeatedly connecting to a host in a tight loop. This backoff applies to all requests sent by the consumer to the broker.	50	Integer
camel.component. .kafka.record- metadata	Whether the producer should store the RecordMetadata results from sending to Kafka. The results are stored in a List containing the RecordMetadata metadata's. The list is stored on a header with the key <code>KafkaConstants#KAFKA_RECORDMETA</code> .	true	Boolean
camel.component. .kafka.request- required-acks	The number of acknowledgments the producer requires the leader to have received before considering a request complete. This controls the durability of records that are sent. The following settings are common: <code>acks=0</code> If set to zero then the producer will not wait for any acknowledgment from the server at all. The record will be immediately added to the socket buffer and considered sent. No guarantee can be made that the server has received the record in this case, and the retries configuration will not take effect (as the client won't generally know of any failures). The offset given back for each record will always be set to -1. <code>acks=1</code> This will mean the leader will write the record to its local log but will respond without awaiting full acknowledgement from all followers. In this case should the leader fail immediately after acknowledging the record but before the followers have replicated it then the record will be lost. <code>acks=all</code> This means the leader will wait for the full set of in-sync replicas to acknowledge the record. This guarantees that the record will not be lost as long as at least one in-sync replica remains alive. This is the strongest available guarantee.	1	String

Name	Description	Default	Type
camel.component.kafka.request-timeout-ms	The amount of time the broker will wait trying to meet the request.required.acks requirement before sending back an error to the client.	30000	Integer
camel.component.kafka.resume-strategy	This option allows the user to set a custom resume strategy. The resume strategy is executed when partitions are assigned (i.e.: when connecting or reconnecting). It allows implementations to customize how to resume operations and serve as more flexible alternative to the seekTo and the offsetRepository mechanisms. See the KafkaConsumerResumeStrategy for implementation details. This option does not affect the auto commit setting. It is likely that implementations using this setting will also want to evaluate using the manual commit option along with this. The option is a org.apache.camel.component.kafka.consumer.support.KafkaConsumerResumeStrategy type.		KafkaConsumerResumeStrategy
camel.component.kafka.retries	Setting a value greater than zero will cause the client to resend any record whose send fails with a potentially transient error. Note that this retry is no different than if the client resent the record upon receiving the error. Allowing retries will potentially change the ordering of records because if two records are sent to a single partition, and the first fails and is retried but the second succeeds, then the second record may appear first.	0	Integer
camel.component.kafka.retry-backoff-ms	Before each retry, the producer refreshes the metadata of relevant topics to see if a new leader has been elected. Since leader election takes a bit of time, this property specifies the amount of time that the producer waits before refreshing the metadata.	100	Integer
camel.component.kafka.sasl-jaas-config	Expose the kafka sasl.jaas.config parameter Example: org.apache.kafka.common.security.plain.PlainLoginModule required username=USERNAME password=PASSWORD;.		String
camel.component.kafka.sasl-kerberos-service-name	The Kerberos principal name that Kafka runs as. This can be defined either in Kafka's JAAS config or in Kafka's config.		String

Name	Description	Default	Type
camel.component .kafka.sasl-mechanism	The Simple Authentication and Security Layer (SASL) Mechanism used. For the valid values see .	GSSAPI	String
camel.component .kafka.schema-registry-u-r-l	URL of the Confluent Platform schema registry servers to use. The format is host1:port1,host2:port2. This is known as schema.registry.url in the Confluent Platform documentation. This option is only available in the Confluent Platform (not standard Apache Kafka).		String
camel.component .kafka.security-protocol	Protocol used to communicate with brokers. SASL_PLAINTEXT, PLAINTEXT and SSL are supported.	PLAINTEXT	String
camel.component .kafka.seek-to	Set if KafkaConsumer will read from beginning or end on startup: beginning : read from beginning end : read from end This is replacing the earlier property seekToBeginning.		String
camel.component .kafka.send-buffer-bytes	Socket write buffer size.	131072	Integer
camel.component .kafka.session-timeout-ms	The timeout used to detect failures when using Kafka's group management facilities.	10000	Integer
camel.component .kafka.shutdown-timeout	Timeout in milliseconds to wait gracefully for the consumer or producer to shutdown and terminate its worker threads.	30000	Integer
camel.component .kafka.specific-avro-reader	This enables the use of a specific Avro reader for use with the Confluent Platform schema registry and the io.confluent.kafka.serializers.KafkaAvroDeserializer. This option is only available in the Confluent Platform (not standard Apache Kafka).	false	Boolean
camel.component .kafka.ssl-cipher-suites	A list of cipher suites. This is a named combination of authentication, encryption, MAC and key exchange algorithm used to negotiate the security settings for a network connection using TLS or SSL network protocol.By default all the available cipher suites are supported.		String

Name	Description	Default	Type
camel.component.kafka.ssl-context-parameters	SSL configuration using a Camel SSLContextParameters object. If configured it's applied before the other SSL endpoint parameters. NOTE: Kafka only supports loading keystore from file locations, so prefix the location with file: in the KeyStoreParameters.resource option. The option is a org.apache.camel.support.jsse.SSLContextParameters type.		SSLContextParameters
camel.component.kafka.ssl-enabled-protocols	The list of protocols enabled for SSL connections. TLSv1.2, TLSv1.1 and TLSv1 are enabled by default.		String
camel.component.kafka.ssl-endpoint-algorithm	The endpoint identification algorithm to validate server hostname using server certificate.	https	String
camel.component.kafka.ssl-key-password	The password of the private key in the key store file. This is optional for client.		String
camel.component.kafka.ssl-keymanager-algorithm	The algorithm used by key manager factory for SSL connections. Default value is the key manager factory algorithm configured for the Java Virtual Machine.	SunX509	String
camel.component.kafka.ssl-keystore-location	The location of the key store file. This is optional for client and can be used for two-way authentication for client.		String
camel.component.kafka.ssl-keystore-password	The store password for the key store file. This is optional for client and only needed if ssl.keystore.location is configured.		String
camel.component.kafka.ssl-keystore-type	The file format of the key store file. This is optional for client. Default value is JKS.	JKS	String
camel.component.kafka.ssl-protocol	The SSL protocol used to generate the SSLContext. Default setting is TLS, which is fine for most cases. Allowed values in recent JVMs are TLS, TLSv1.1 and TLSv1.2. SSL, SSLv2 and SSLv3 may be supported in older JVMs, but their usage is discouraged due to known security vulnerabilities.		String

Name	Description	Default	Type
camel.component.kafka.ssl-provider	The name of the security provider used for SSL connections. Default value is the default security provider of the JVM.		String
camel.component.kafka.ssl-trustmanager-algorithm	The algorithm used by trust manager factory for SSL connections. Default value is the trust manager factory algorithm configured for the Java Virtual Machine.	PKIX	String
camel.component.kafka.ssl-truststore-location	The location of the trust store file.		String
